(57) **ABSTRACT**

The present invention relates to polynucleotides encoding adult plant pathogen resistance proteins. Also provided are transgenic plants expressing these polynucleotides to enhance the resistance of the plants to pathogens.

RESISTANCE GENES

FIELD OF THE INVENTION

The present invention relates to polynucleotides encoding adult plant pathogen resistance proteins. Also provided are transgenic plants expressing these polynucleotides to enhance the resistance of the plants to pathogens.

BACKGROUND OF THE INVENTION

Numerous genes conferring resistance to pathogens have been identified and used in plant breeding. However, single-gene pathogen resistance in plants often becomes ineffective due to the emergence of new virulent races of the disease agent. In contrast, durable disease resistance in plants is generally thought to be controlled by multiple genes.

The wheat (*Triticum aestivum*) quantitative trait locus, Lr34, provides durable adult plant resistance to the biotrophic fungi causing the diseases leaf rust, stripe rust, stem rust and powdery mildew (Dyck, 1977 and 1987; German and Kolmer, 1992; Bossolini et al. 2006; Spielmeier et al. 2008). This is despite the limitation that it is not effective at the seedling stage under normal field conditions. Cultivars with the resistance locus Lr34 such as Frontana have had effective durable resistance to the leaf rust fungus *Puccinia triticina* Eriks (Dyck et al., 1966; Singh and Rajaram, 1994). To date, isolates of *P. triticina* with complete virulence to Lr34 have not been detected (Kolmer et al., 2003).

Lr34 resistance has remained genetically inseparable from Yr18 that confers resistance to stripe rust (*P. striiformis*) (Singh, 1992a; McIntosh, 1992). Co-segregation of Lr34/Yr18 with other traits such as leaf tip necrosis (Ltn1), powdery mildew (recently designated Pm38), tolerance to barley yellow dwarf virus (Bdvl) and spot blotch (*Bipolaris sorokiniana*) have been documented (Singh, 1992a, b; McIntosh, 1992; Joshi et al., 2004; Spielmeier et al., 2005; Liang et al., 2006). These multi-pathogen resistance traits have made the Lr34/Yr18 locus one of the most valuable gene regions for disease resistance breeding in wheat.

A few rust resistance genes have been isolated and cloned from wheat (Feuillet et al., 2003; Huang et al., 2003; Cloutier et al., 2007) and other cereals (Collins et al., 1999; Brueggeman et al., 2002) and are predominantly from the nucleotide binding site-leucine rich repeat (NB-LRR) class of major resistance (R) genes. The only known exception is the barley Rpgl rust resistance gene which encodes a protein kinase. These genes encode gene-for-gene resistance against single pathogens and generally lead to hypersensitive responses in the plant tissues upon infection. In contrast, Lr34 confers a broad spectrum resistance against several obligate biotrophic pathogens including fungi from the Ascomycetes and Basidiomycetes. Rubiales and Niks (1995) reported that Lr34 is associated with reduced intercellular hyphal growth but not with a hypersensitive response or papilla formation.

The molecular basis of quantitative non-race-specific, adult plant pathogen resistance-type or partial resistance encoded by genetic systems such as, for example, Lr34 therefore remains unknown.

SUMMARY OF THE INVENTION

The present inventors have identified genes and polypeptides which confer enhanced plant pathogen resistance to adult plants.

Accordingly, the present invention provides a transgenic plant which has integrated into its genome an exogenous

2

polynucleotide encoding an adult plant pathogen resistance polypeptide and/or an exogenous polynucleotide which increases transcription of an endogenous gene encoding an adult plant pathogen resistance polypeptide.

In a preferred embodiment, the plant has accelerated senescence of flag leaf tips when compared to an isogenic plant lacking the exogenous polynucleotide.

In another preferred embodiment, the plant has enhanced resistance to a plant pathogen when compared to an isogenic plant lacking the exogenous polynucleotide.

In yet a further preferred embodiment, the polypeptide comprises amino acids having a sequence as provided in SEQ ID NO:1, a biologically active fragment thereof, or an amino acid sequence which is at least 40% identical, more preferably at least 80% identical, more preferably at least 90% identical, and even more preferably at least 95% identical, to SEQ ID NO:1. More preferably, the polypeptide comprises amino acids having a sequence as provided in SEQ ID NO:1.

In another preferred embodiment, the polynucleotide comprises nucleotides having a sequence as provided in SEQ ID NO:2, a sequence which is at least 40% identical to SEQ ID NO:2, and/or a sequence which hybridizes to SEQ ID NO:2.

In another embodiment, the exogenous polynucleotide which increases transcription of an endogenous gene encoding an adult plant pathogen resistance polypeptide is a genetic element, such as a promoter, which enhances the function of the endogenous gene promoter. Alternatively, the exogenous polynucleotide which increases transcription of an endogenous gene encoding an adult plant pathogen resistance polypeptide encodes a transcription factor which enhances expression of the endogenous gene.

Preferably, the plant is a cereal plant. Examples of transgenic cereal plants of the invention include, but are not limited to wheat, barley, maize, rice, oats and triticale. In a particularly preferred embodiment, the plant is wheat.

Examples of plant pathogens include, but are not limited to viruses, bacteria and fungi.

In a preferred embodiment, the pathogen is a biotrophic fungus. Examples of biotrophic fungi include, but are not limited to, *Fusarium graminearum* (which causes head blight), *Erysiphe graminis* f. sp. *tritici* (which causes powdery mildew), *Bipolaris sorokiniana* (which causes spot blotch), *Puccinia graminis* f. sp. *tritici* (which causes stem rust), *Puccinia striiformis* (which causes stripe rust) and *Puccinia recondite* f. sp. *tritici* (which causes leaf rust).

In an embodiment, the pathogen is barley yellow dwarf virus (BYDV).

In an embodiment, the plant comprises one or more further exogenous polynucleotides encoding a plant pathogen resistance polypeptide. Examples of such genes include, but are not limited to, Lr1, Lr3, Lr2a, Lr3ka, Lr1l, Lr13, Lr16, Lr17, Lr18, Lr21 and LrB.

In another aspect, the present invention provides a process for identifying a polynucleotide encoding a plant pathogen resistance polypeptide comprising:

(i) obtaining a polynucleotide operably linked to a promoter, the polynucleotide encoding a polypeptide comprising amino acids having a sequence as provided in SEQ ID NO:1, a biologically active fragment thereof, or an amino acid sequence which is at least 40% identical to SEQ ID NO:1,

(ii) introducing the polynucleotide into a plant,

(iii) determining whether the level of resistance to a plant pathogen is modified relative to an isogenic plant lacking the polynucleotide, and

(iv) optionally, selecting a polynucleotide which when expressed enhances resistance to the plant pathogen.

Preferably, the polynucleotide comprises nucleotides having a sequence as provided in SEQ ID NO:2, a sequence which is at least 40% identical to SEQ ID NO:2, and/or a sequence which hybridizes to SEQ ID NO:2.

Preferably, the plant is a cereal plant.

Preferably, the cereal plant is a wheat plant.

In a preferred embodiment, the polypeptide is a plant polypeptide or mutant thereof.

In a further embodiment, step (ii) further comprises stably integrating the polynucleotide operably linked to a promoter into the genome of the plant.

In yet another aspect, the present invention provides a substantially purified and/or recombinant adult plant pathogen resistance polypeptide.

In a preferred embodiment, the polypeptides comprises amino acids having a sequence as provided in SEQ ID NO:1, a biologically active fragment thereof, or an amino acid sequence which is at least 40% identical, more preferably at least 80% identical, more preferably at least 90% identical, and even more preferably at least 95% identical, to SEQ ID NO:1.

In a preferred embodiment, the polypeptide lacks a phenylalanine residue or any amino acid at a position corresponding to amino acid number 546 of SEQ ID NO:4.

In another preferred embodiment, the polypeptide has an amino acid other than a tyrosine residue at a position corresponding to amino acid number 634 of SEQ ID NO:4. More preferably, the polypeptide comprises a histidine residue at a position corresponding to amino acid number 634 of SEQ ID NO:4.

Also provided is a fusion protein further comprising at least one other polypeptide sequence. The at least one other polypeptide may be, for example, a polypeptide that enhances the stability of a polypeptide of the present invention, or a polypeptide that assists in the purification or detection of the fusion protein.

In a further aspect, the present invention provides an isolated and/or exogenous polynucleotide comprising nucleotides having a sequence as provided in SEQ ID NO:2, a sequence which is at least 40% identical to SEQ ID NO:2, a sequence encoding a polypeptide of the invention, and/or a sequence which hybridizes to SEQ ID NO:2.

Preferably, the polynucleotide comprises a sequence of nucleotides which hybridizes to SEQ ID NO:2 under stringent conditions.

Preferably, the polynucleotide hybridizes along the full length of a polynucleotide consisting of nucleotides having the sequence of SEQ ID NO:2.

Preferably, the polynucleotide encodes an adult plant pathogen resistance polypeptide.

In a further aspect, the present invention provides a chimeric vector comprising the polynucleotide of the invention.

Preferably, the polynucleotide is operably linked to a promoter.

In a further aspect, the present invention provides a recombinant cell comprising an exogenous polynucleotide of the invention and/or a vector of the invention.

The cell can be any cell type such as, but not limited to, a plant cell, a bacterial cell, an animal cell or a yeast cell.

Preferably, the cell is a plant cell. More preferably, the plant cell is a cereal plant cell. Even more preferably, the cereal plant cell is a wheat cell.

In a further aspect, the present invention provides a method of producing the polypeptide of the invention, the method comprising expressing in a cell or cell free expression system the polynucleotide of the invention.

Preferably, the method further comprises isolating the polypeptide.

In yet another aspect, the present invention provides a transgenic non-human organism comprising an exogenous polynucleotide of the invention, a vector of the invention and/or a recombinant cell of the invention.

Preferably, the transgenic non-human organism is a plant.

In another aspect, the present invention provides a method of producing the cell of the invention, the method comprising the step of introducing the polynucleotide of the invention, or a vector of the invention, into a cell.

Preferably, the cell is a plant cell.

In a further aspect, the present invention provides a method of producing a transgenic plant, the method comprising regenerating a transgenic plant from the cell of the invention.

Also provided is the use of the polynucleotide of the invention, or a vector of the invention, to produce a recombinant cell.

Further, provided is the use of the polynucleotide of the invention, or a vector of the invention, to produce a transgenic plant.

Preferably, the transgenic plant has accelerated senescence of flag leaf tips when compared to an isogenic plant lacking the exogenous polynucleotide and/or vector, and/or has enhanced resistance to a plant pathogen when compared to an isogenic plant lacking the exogenous polynucleotide and/or vector.

In another aspect, the present invention provides a transgenic plant, or progeny thereof, produced using a method of the invention.

In a further aspect, the present invention provides a plant part of the plant of the invention.

Examples of such plant parts include, but are not limited to, leaves, roots, stems and/or seeds. In a preferred embodiment, the plant part is a seed that comprises an exogenous polynucleotide encoding an adult plant pathogen resistance polypeptide.

In another aspect, the present invention provides a method of producing a plant part, the method comprising,

- a) growing a plant of the invention, and
- b) harvesting the plant part.

In yet a further aspect, the present invention provides a method of producing flour, wholemeal, starch or other product obtained from seed, the method comprising;

- a) obtaining seed of the invention, and
- b) extracting the flour, wholemeal, starch or other product.

In another aspect, the present invention provides a product produced from a plant of the invention and/or a plant part of the invention.

In one embodiment, the product is a food product. Examples include, but are not limited to, flour, starch, leavened or unleavened breads, pasta, noodles, animal fodder, breakfast cereals, snack foods, cakes, malt, beer, pastries and foods containing flour-based sauces.

In another embodiment, the product is a non-food product. Examples include, but are not limited to, films, coatings, adhesives, building materials and packaging materials.

In a further aspect, the present invention provides a method of preparing a food product of the invention, the method comprising mixing seed, or flour, wholemeal or starch from said seed, with another ingredient.

In a further aspect, the present invention provides a method of preparing malt, comprising the step of germinating the seed of the invention.

In another embodiment, the present invention provides a composition comprising a polypeptide of the invention, a

polynucleotide of the invention, a vector of the invention, and/or recombinant cell of the invention, and one or more acceptable carriers.

In another aspect, the present invention provides a substantially purified antibody, or fragment thereof, that specifically binds a polypeptide of the invention.

Also provided is a method of identifying a compound that binds to a polypeptide comprising amino acids having a sequence as provided in SEQ ID NO:1 or SEQ ID NO:4, a biologically active fragment thereof, or an amino acid sequence which is at least 40% identical to SEQ ID NO:1 and/or SEQ ID NO:4, the method comprising:

- i) contacting the polypeptide with a candidate compound, and
- ii) determining whether the compound binds the polypeptide.

Further, provided is a method of identifying a compound that is transported across a cell membrane by a polypeptide comprising amino acids having a sequence as provided in SEQ ID NO:1 or SEQ ID NO:4, a biologically active fragment thereof, or an amino acid sequence which is at least 40% identical to SEQ ID NO:1 and/or SEQ ID NO:4, the method comprising:

- i) contacting the polypeptide present in a cell membrane with a candidate compound,
- ii) determining whether the polypeptide transports the compound across the cell membrane.

Preferably, the polypeptide is expressed in a cell.

Preferably, the cell is a plant cell.

In an embodiment, the method further comprises comparing the binding, and/or transport, of the compound to a first polypeptide comprising an amino acid sequence provided as SEQ ID NO:1 to a second polypeptide comprising an amino acid sequence provided as SEQ ID NO:4.

In a further aspect, the present invention provides an isolated and/or exogenous polynucleotide which, when present in a cell of a plant, decreases the expression of at least one gene that hybridises under stringent conditions to a nucleic acid molecule encoding a polypeptide comprising amino acids having a sequence as provided in SEQ ID NO:1 or SEQ ID NO:4, a biologically active fragment thereof, or an amino acid sequence which is at least 40% identical to SEQ ID NO:1 and/or SEQ ID NO:4, said decreased expression being relative to an otherwise isogenic cell of a plant that lacks said polynucleotide.

In an embodiment, the polynucleotide encodes an adult plant pathogen resistance polypeptide.

Preferably, the polynucleotide of this aspect is operably linked to a promoter capable of directing expression of the polynucleotide in a cell of a plant.

Preferably, the polynucleotide of this aspect is an antisense polynucleotide, a sense polynucleotide, a catalytic polynucleotide, an artificial microRNA or a duplex RNA molecule.

In a further aspect, the present invention provides a method of identifying a plant comprising a gene encoding an adult plant pathogen resistance polypeptide, the method comprising

- i) amplifying and/or sequencing, from a sample of the plant, at least a portion of a polynucleotide which encodes a polypeptide comprising amino acids having a sequence as provided in SEQ ID NO:1 or SEQ ID NO:4, a biologically active fragment thereof, or an amino acid sequence which is at least 40% identical to SEQ ID NO:1 and/or SEQ ID NO:4,
- ii) determining if the plant comprises a polynucleotide encoding an adult plant pathogen resistance polypeptide.

As will be apparent, preferred features and characteristics of one aspect of the invention are applicable to many other aspects of the invention.

Throughout this specification the word “comprise”, or variations such as “comprises” or “comprising”, will be understood to imply the inclusion of a stated element, integer or step, or group of elements, integers or steps, but not the exclusion of any other element, integer or step, or group of elements, integers or steps.

The invention is hereinafter described by way of the following non-limiting Examples and with reference to the accompanying figures.

BRIEF DESCRIPTION OF THE ACCOMPANYING DRAWINGS

FIG. 1. Consensus genetic map of wheat chromosome 7D including Lr34 based on three high-resolution mapping populations defined a 0.15 cM target interval for Lr34 between XWSNP3 and XcsLVE17. Relative positions of molecule markers are shown together with the observed recombinational distances in cM.

FIG. 2. Schematic of expanded view of part of wheat chromosome 7DS between XWSNP3 and XcsLVE17 showing relative positions of open reading frames. The corresponding physical target interval sequenced on the +Lr34 cultivar ‘Chinese Spring’ contained ten candidate genes, nine of which are represented in the Figure by arrows. Numbers refer to the respective nucleotide positions within the 420 kb sequenced interval. Abbreviations: Gly, glycosyl transferase; Cyst, cysteine proteinase; Cyt, Cytochrome P450; LecK, lectin kinase; ABC, ABC transporter; Hex, hexose carrier.

FIG. 3. Gene structure of Lr34. Open boxes indicate exons, while introns are shown as adjoining lines. Marks indicate the positions of mutation sites of the mutants labelled 2B, 2F, 2G, 3E, 4C, 4D, m19 and m21. The three sequence differences between susceptible and resistant alleles of Lr34 are indicated: +Lr34 resistant allele from Chinese Spring, -Lr34 susceptible allele from Renan.

FIG. 4. Lr34 protein sequence and polymorphisms between resistant and susceptible cultivars. Amino acid sequence of the Lr34 protein (susceptible allele) from cultivar ‘Renan’. The two amino acids that are altered in the resistant allele are highlighted. Other boxes indicate the positions of the highly conserved motifs within the nucleotide binding domains. Motifs: “Walker A” GPPGCGKS (amino acids 168-175) (SEQ ID NO:50) and GVSGAGKT (amino acids 847-854) (SEQ ID NO:51); “ABC signature” ISGGQKKRLTTA (amino acids 307-318) (SEQ ID NO:52) and LSMEQRKRLTIA (amino acids 954-965) (SEQ ID NO:53); “Walker B” AYFMD (amino acids 327-331) (SEQ ID NO:54) and IILMD (amino acids 974-978) (SEQ ID NO:55). Amino acid changes in the resistant allele of Lr34 in wheat cultivar Chinese Spring are deletion of amino acid 546 (Phe (F)) and substitution of amino acid 634 (tyrosine (Y)) to histidine. Underlined portions are the two transmembrane domains (amino acids 502-750 and 1152-1392).

FIG. 5. Schematic representation of the Lr34 protein showing the two nucleotide binding domains (NBD) and the two transmembrane domains. The two diagnostic polymorphisms between resistant and susceptible alleles in the first transmembrane domain are indicated by stars.

FIG. 6. Lr34 amino acid sequence alignment. Alignment of Lr34 of cultivar Renan with rice PDR23 (Os12g0512700) (SEQ ID NO:47) and *Arabidopsis* PDR5 (At3g53480) (SEQ ID NO:48) and PDR9 (At2g37280) (SEQ ID NO:49). Resi-

dues identical in all the four transporters are indicated. Rice PDR23 has been newly annotated according to the wheat Lr34 cDNA.

FIG. 7. Expression analysis of Lr34. Semi-quantitative RT-PCR using a probe from the 5' end of the gene. Leaves of the near isogenic lines 'Thatcher' and 'Thatcher Lr34' were harvested at the seedling stage after 14 days and of adult flag leaves on 53 and 63 days old plants. Adult leaves were halved to separately study expression levels of leaf base and leaf tip. Abbreviations: TH='Thatcher'; TH Lr34='Thatcher Lr34'; GAPDH=Glyceraldehyde 3-phosphate dehydrogenase.

FIG. 8. Lr34 regulates senescence of flag leaves. Northern Blot using HvS40 on 63 days old flag leaves of the near isogenic lines 'Thatcher' and 'Thatcher Lr34' and the azide induced Lr34 mutants 2B, 2F, 2G, 3E, 4C and 4E. TH='Thatcher'; TH Lr34='Thatcher Lr34'.

KEY TO THE SEQUENCE LISTING

SEQ ID NO:1—Amino acid sequence of Lr34 protein (resistant allele) from *Triticum aestivum* cv Chinese spring.

SEQ ID NO:2—Nucleotide coding sequence for Lr34 from *Triticum aestivum* cv Chinese spring.

SEQ ID NO:3—Nucleotide sequence of the Lr34 gene (genomic sequence) from *Triticum aestivum* cv Chinese spring. 24 exons are present which encode the Lr34 protein:

exon 1 starts at nucleotide 3042 and ends at nucleotide 3316; exon 2 starts at nucleotide 3416 and ends at nucleotide 3539; exon 3 starts at nucleotide 3693 and ends at nucleotide 3778; exon 4 starts at nucleotide 3934 and ends at nucleotide 4018; exon 5 starts at nucleotide 6527 and ends at nucleotide 6686; exon 6 starts at nucleotide 6784 and ends at nucleotide 6860; exon 7 starts at nucleotide 7119 and ends at nucleotide 7172; exon 8 starts at nucleotide 7271 and ends at nucleotide 7361; exon 9 starts at nucleotide 7439 and ends at nucleotide 7740; exon 10 starts at nucleotide 7833 and ends at nucleotide 8108; exon 11 starts at nucleotide 8187 and ends at nucleotide 8497; exon 12 starts at nucleotide 8583 and ends at nucleotide 8743; exon 13 starts at nucleotide 8825 and ends at nucleotide 8928; exon 14 starts at nucleotide 9015 and ends at nucleotide 9168; exon 15 starts at nucleotide 9606 and ends at nucleotide 9513; exon 16 starts at nucleotide 9808 and ends at nucleotide 9581; exon 17 starts at nucleotide 9985 and ends at nucleotide 10317;

exon 18 starts at nucleotide 10427 and ends at nucleotide 10717;

exon 19 starts at nucleotide 12159 and ends at nucleotide 12242;

exon 20 starts at nucleotide 12711 and ends at nucleotide 12844;

exon 21 starts at nucleotide 12995 and ends at nucleotide 13222;

exon 22 starts at nucleotide 13318 and ends at nucleotide 13489;

exon 23 starts at nucleotide 13569 and ends at nucleotide 13823; and

exon 24 starts at nucleotide 14613 and ends at nucleotide 14939.

SEQ ID NO:4—Amino acid sequence of Lr34 protein (susceptible allele) from *Triticum aestivum* "Renan".

SEQ ID NO:5—Nucleotide coding sequence for Lr34 (susceptible allele) from *Triticum aestivum* "Renan".

SEQ ID NO:6—Genomic DNA for *Aegilops tauschii* Lr34 equivalent. Coding region starts at nucleotide 2426 and ends at nucleotide 14212.

SEQ ID NO:7—EST of *Triticum aestivum* Lr34 (GenBank Accession No. CJ669561).

SEQ ID NO:8—EST of *Triticum aestivum* Lr34 (GenBank Accession No. DR733734).

SEQ ID NO:9—EST of *Triticum aestivum* Lr34 (GenBank Accession No. CJ562397).

SEQ ID NO:10—EST of *Triticum aestivum* Lr34 (GenBank Accession No. CV773074).

SEQ ID NO:11—EST for *Hordeum vulgare* Lr34 (GenBank Accession No. BU991506).

SEQ ID NO's: 12-46—Oligonucleotide primers.

SEQ ID NO:47—Rice ABC transporter PDR23.

SEQ ID NO:48—*Arabidopsis thaliana* ABC transporter PDR5.

SEQ ID NO:49—*Arabidopsis thaliana* ABC transporter PDR9.

SEQ ID NO: 50—N-terminal Walker A sequence of Lr34.

SEQ ID NO: 51—C-terminal Walker A sequence of Lr34.

SEQ ID NO: 52—N-terminal ABC signature sequence of Lr34.

SEQ ID NO: 53—C-terminal ABC signature sequence of Lr34.

SEQ ID NO: 54—N-terminal Walker B sequence of Lr34.

SEQ ID NO: 55—C-terminal Walker B sequence of Lr34.

SEQ ID NO: 56—Consensus Walker A sequence of ABC transporters.

SEQ ID NO: 57—Consensus Walker B sequence of ABC transporters.

SEQ ID NO: 58—Consensus ABC signature sequence of ABC transporters.

SEQ ID NO:59—PDR signature sequence 1.

SEQ ID NO:60—PDR signature sequence 2.

SEQ ID NO:61—PDR signature sequence 3.

SEQ ID NO:62—PDR signature sequence 4.

SEQ ID NO:63—Polypeptide encoded by Lr34 homeolog on wheat chromosome 7B.

SEQ ID NO:64—Open reading frame encoding Lr34 homeolog on wheat chromosome 7B.

DETAILED DESCRIPTION OF THE INVENTION

General Techniques

Unless specifically defined otherwise, all technical and scientific terms used herein shall be taken to have the same meaning as commonly understood by one of ordinary skill in the art (e.g., in cell culture, molecular genetics, plant molecular biology, protein chemistry, and biochemistry).

Unless otherwise indicated, the recombinant protein, cell culture, and immunological techniques utilized in the present invention are standard procedures, well known to those skilled in the art. Such techniques are described and explained throughout the literature in sources such as, J. Perbal, A Practical Guide to Molecular Cloning, John Wiley and Sons (1984), J. Sambrook et al., Molecular Cloning: A Laboratory Manual, Cold Spring Harbour Laboratory Press (1989), T. A. Brown (editor), Essential Molecular Biology: A Practical Approach, Volumes 1 and 2, IRL Press (1991), D. M. Glover and B. D. Hames (editors), DNA Cloning: A Practical Approach, Volumes 1-4, IRL Press (1995 and 1996), and F. M. Ausubel et al. (editors), Current Protocols in Molecular Biology, Greene Pub. Associates and Wiley-Interscience (1988, including all updates until present), Ed Harlow and David Lane (editors) Antibodies: A Laboratory Manual, Cold Spring Harbour Laboratory, (1988), and J. E. Coligan et al. (editors) Current Protocols in Immunology, John Wiley & Sons (including all updates until present).

Polypeptides/Peptides

By "substantially purified polypeptide" or "purified polypeptide" we mean a polypeptide that has generally been

separated from the lipids, nucleic acids, other peptides, and other contaminating molecules with which it is associated in its native state. Preferably, the substantially purified polypeptide is at least 90% free from other components with which it is naturally associated.

The term “recombinant” in the context of a polypeptide refers to the polypeptide when produced by a cell, or in a cell-free expression system, in an altered amount or at an altered rate compared to its native state. In one embodiment, the cell is a cell that does not naturally produce the polypeptide. However, the cell may be a cell which comprises a non-endogenous gene that causes an altered amount of the polypeptide to be produced. A recombinant polypeptide of the invention includes polypeptides which have not been separated from other components of the transgenic (recombinant) cell, or cell-free expression system, in which it is produced, and polypeptides produced in such cells or cell-free systems which are subsequently purified away from at least some other components. In an embodiment, a “recombinant polypeptide” is a polypeptide made by the expression of a recombinant polynucleotide in a cell, preferably a plant cell and more preferably a cereal plant cell.

The terms “polypeptide” and “protein” are generally used interchangeably.

As used herein, the term “adult plant pathogen resistance polypeptide” refers to a protein encoded by a gene which ordinarily confers upon an adult plant an enhanced resistance to a plant pathogen when compared to an isogenic plant lacking said gene, and which confers on seedlings of the same plant substantially less or no resistance to the same pathogen when the plant is grown in normal field conditions. This term also refers to the naturally produced protein (or wild type protein from which a mutant protein is derived) encoded by a gene conferring upon an adult plant (for example, of the wheat cultivar Frontana), but not a seedling, when grown in normal field conditions, enhanced resistance to a plant pathogen. Typically, adult plant pathogen resistance polypeptides do not confer a hypersensitive response on the plants in the presence of the pathogen, and the resistance is durable in the field over time. As used herein, “adult plant” refers to a plant that has commenced the reproductive phase of growth and development. In an embodiment, less than half of the protein is produced per gram dry weight in leaves of a seedling when compared to leaves of the adult plant. Examples of plant pathogens for which resistance is enhanced include, but are not limited to, *Fusarium graminearum*, *Erysiphe graminis* f. sp. *tritici*, *Bipolaris sorokiniana*, *Puccinia graminis* f. sp. *tritici*, *Puccinia striiformis* and *Puccinia recondite* f. sp. *tritici*.

The % identity of a polypeptide is determined by GAP (Needleman and Wunsch, 1970) analysis (GCG program) with a gap creation penalty=5, and a gap extension penalty=0.3. The query sequence is at least 150 amino acids in length, and the GAP analysis aligns the two sequences over a region of at least 150 amino acids. More preferably, the query sequence is at least 500 amino acids in length, and the GAP analysis aligns the two sequences over a region of at least 500 amino acids. More preferably, the query sequence is at least 1,000 amino acids in length and the GAP analysis aligns the two sequences over a region of at least 1,000 amino acids. Even more preferably, the query sequence is at least 1,250 amino acids in length and the GAP analysis aligns the two sequences over a region of at least 1,250 amino acids. Even more preferably, the GAP analysis aligns two sequences over their entire length.

As used herein a “biologically active” fragment is a portion of a polypeptide of the invention which maintains a defined

activity of the full-length polypeptide. Biologically active fragments can be any size as long as they maintain the defined activity but are preferably at least 1000 or at least 1200 amino acid residues long. Preferably, the biologically active fragment maintains at least 10% of the activity of the full length protein.

The phrase “enhanced resistance to a plant pathogen” is used herein as a relative term such that a plant of the invention has an increased level of resistance to a plant pathogen when compared to a genetically identical lacking the exogenous polynucleotide. Enhanced resistance can be determined by a number of methods known in the art such as analysing the plants for the amount of pathogen and/or analysing plant growth or the amount of damage to a plant in the presence of the pathogen.

As used herein, the term “has accelerated senescence of flag leaf tips” refers to an early onset of aging of the extremity of the lowermost leaf on the stem of a plant. This is used herein as a relative term such that a plant of the invention has an increased senescence of flag leaf tips when compared to a genetically identical flag leaf lacking the exogenous polynucleotide. Accelerated senescence of flag leaf tips can be measured by any means known in the art, such as that described in Example 5.

With regard to a defined polypeptide, it will be appreciated that % identity figures higher than those provided above will encompass preferred embodiments. Thus, where applicable, in light of the minimum % identity figures, it is preferred that the polypeptide comprises an amino acid sequence which is at least 60%, more preferably at least 65%, more preferably at least 70%, more preferably at least 75%, more preferably at least 76%, more preferably at least 80%, more preferably at least 85%, more preferably at least 90%, more preferably at least 91%, more preferably at least 92%, more preferably at least 93%, more preferably at least 94%, more preferably at least 95%, more preferably at least 96%, more preferably at least 97%, more preferably at least 98%, more preferably at least 99%, more preferably at least 99.1%, more preferably at least 99.2%, more preferably at least 99.3%, more preferably at least 99.4%, more preferably at least 99.5%, more preferably at least 99.6%, more preferably at least 99.7%, more preferably at least 99.8%, and even more preferably at least 99.9% identical to the relevant nominated SEQ ID NO.

As used herein, the phrase “at a position corresponding to amino acid number” or variations thereof refers to the relative position of the amino acid compared to surrounding amino acids. In this regard, in some embodiments a polypeptide of the invention may have deletional or substitutional mutations which alters the relative positioning of the amino acid when aligned against, for instance, SEQ ID NO:1 and/or SEQ ID NO:4. For example, the polypeptide with a sequence as provided in SEQ ID NO:1 has a single amino acid deletion when compared to the polypeptide with a sequence as provided in SEQ ID NO:4, namely the phenylalanine at position number 546 of SEQ ID NO:4 is missing in SEQ ID NO:1 and has not been substituted with another amino acid. As a result, the skilled person will appreciate that amino acid number 634 of SEQ ID NO:4 (Y) corresponds to amino acid number 633 of SEQ ID NO:4 (H).

Amino acid sequence mutants of the polypeptides of the present invention can be prepared by introducing appropriate nucleotide changes into a nucleic acid of the present invention, or by in vitro synthesis of the desired polypeptide. Such mutants include, for example, deletions, insertions or substitutions of residues within the amino acid sequence. A combination of deletion, insertion and substitution can be made to arrive at the final construct, provided that the final peptide

product possesses the desired characteristics. Preferred amino acid sequence mutants have only one, two, three, four or less than 10 amino acid changes relative to the reference wildtype polypeptide.

Mutant (altered) peptides can be prepared using any technique known in the art. For example, a polynucleotide of the invention can be subjected to in vitro mutagenesis. Such in vitro mutagenesis techniques include sub-cloning the polynucleotide into a suitable vector, transforming the vector into a "mutator" strain such as the *E. coli* XL-1 red (Stratagene) and propagating the transformed bacteria for a suitable number of generations. In another example, the polynucleotides of the invention are subjected to DNA shuffling techniques as broadly described by Harayama (1998). Products derived from mutated/changed DNA can readily be screened using techniques described herein to determine if they possess pathogen resistance and/or ABC transporter activity.

In designing amino acid sequence mutants, the location of the mutation site and the nature of the mutation will depend on characteristic(s) to be modified. The sites for mutation can be modified individually or in series, e.g., by (1) substituting first with conservative amino acid choices and then with more radical selections depending upon the results achieved, (2) deleting the target residue, or (3) inserting other residues adjacent to the located site.

Amino acid sequence deletions generally range from about 1 to 15 residues, more preferably about 1 to 10 residues and typically about 1 to 5 contiguous residues.

Substitution mutants have at least one amino acid residue in the polypeptide molecule removed and a different residue inserted in its place. The sites of greatest interest for substitutional mutagenesis include sites identified as the active site(s). Other sites of interest are those in which particular residues obtained from various strains or species are identical. These positions may be important for biological activity. These sites, especially those falling within a sequence of at least three other identically conserved sites, are preferably substituted in a relatively conservative manner. Such conservative substitutions are shown in Table 1 under the heading of "exemplary substitutions".

In a preferred embodiment a mutant/variant polypeptide has one or two or three or four conservative amino acid changes when compared to a naturally occurring polypeptide. Details of conservative amino acid changes are provided in Table 1. In a preferred embodiment, the changes are not in one or more of the motifs which are highly conserved between the different polypeptides provided herewith. As the skilled person would be aware, such minor changes can reasonably be predicted not to alter the activity of the polypeptide when expressed in a recombinant cell.

TABLE 1

Exemplary substitutions.	
Original Residue	Exemplary Substitutions
Ala (A)	val; leu; ile; gly
Arg (R)	lys
Asn (N)	gln; his
Asp (D)	glu
Cys (C)	ser
Gln (Q)	asn; his
Glu (E)	asp

Tyr (Y)	trp; phe
Val (V)	ile; leu; met; phe, ala

In an embodiment, the protein of the invention is a PDR (pleiotropic drug resistance homolog) ABC transporter and comprises two nucleotide binding domains (NBD) and two transmembrane domains configured as shown in FIG. 5.

The primary amino acid sequence of Lr34 can be used to design variants/mutants thereof based on comparisons with closely related ABC transporters. As the skilled addressee will appreciate, residues highly conserved amongst closely related PDR ABC transporters are less likely to be able to be altered, especially with non-conservative substitutions, and activity maintained than less conserved residues. Such conserved regions and possible substitutions are described by Rae (2007), van den Brule and Smart (2002) and Verrier et al. (2008). The polypeptide generally comprises two Walker A boxes (GX₄GK[ST]) (SEQ ID NO:56) (corresponds to SEQ ID NO's: 50 and 51 of Lr34) and two Walker B boxes ((hydrophobic)₄[DE]) (SEQ ID NO:57) (corresponds to SEQ ID NO's: 54 and 55 of Lr34), and two ABC signature motifs ([LIVMFY][S][SGM][GE][X₃][RKA])[LIVMYA][X][LIVFMT][AG]) (SEQ ID NO:58) (corresponds to SEQ ID NO's: 52 and 53 of Lr34), with each NBD comprising, in order from the N-terminus, a Walker A, ABC signature and Walker B motif (see, for example, FIG. 4). In the above sequences X may be any amino acid, and may be independently the same or different.

Furthermore, the polypeptide generally comprises a PDR signature 1 (LLLGPP) (SEQ ID NO:59) which is immediately N-terminal to and slightly overlaps with the N-terminal Walker A box; PDR signature 2 (GLDSST) (SEQ ID NO:60) which starts about four residues C-terminal to the N-terminal Walker B box; PDR signature 3 (GLD[AT]R[AS]AAIV[MI]R) (SEQ ID NO:61) which starts about four residues C-terminal to the C-terminal Walker B box; and PDR signature 4 (VCTIHQPS) (SEQ ID NO:62) which starts about 86 residues C-terminal to PDR signature 3.

In an embodiment, the polypeptide of the invention comprises one or more of the amino acids motifs provided as SEQ ID NO's: 56 to 58, preferably two copies of all three. More preferably, the polypeptide of the invention comprises one or more of the amino acids motifs provided as SEQ ID NO's: 50 to 55, preferably all six.

In addition, in yet a further embodiment the polypeptide of the invention comprises one or more of the amino acids motifs provided as SEQ ID NO's: 59 to 62, preferably all four.

Sources of naturally occurring variants of SEQ ID NO:1 which confer resistance as described herein are outlined in Table 5. Based on the information provided herein, the skilled person could readily determine the amino acid sequence of these naturally occurring variants, as well as polynucleotides encoding therefor.

Also included within the scope of the invention are polypeptides of the present invention which are differentially

modified during or after synthesis, e.g., by biotinylation, benzylation, glycosylation, acetylation, phosphorylation, amidation, derivatization by known protecting/blocking groups, proteolytic cleavage, linkage to an antibody molecule or other cellular ligand, etc. The polypeptides may be post-translationally modified in a cell, for example by phosphorylation, which may modulate its activity. These modifications may serve to increase the stability and/or bioactivity of the polypeptide of the invention.

Polypeptides of the present invention can be produced in a variety of ways, including production and recovery of natural polypeptides, production and recovery of recombinant polypeptides, and chemical synthesis of the polypeptides. In one embodiment, an isolated polypeptide of the present invention is produced by culturing a cell capable of expressing the polypeptide under conditions effective to produce the polypeptide, and recovering the polypeptide. A preferred cell to culture is a recombinant cell of the present invention. Effective culture conditions include, but are not limited to, effective media, bioreactor, temperature, pH and oxygen conditions that permit polypeptide production. An effective medium refers to any medium in which a cell is cultured to produce a polypeptide of the present invention. Such medium typically comprises an aqueous medium having assimilable carbon, nitrogen and phosphate sources, and appropriate salts, minerals, metals and other nutrients, such as vitamins. Cells of the present invention can be cultured in conventional fermentation bioreactors, shake flasks, test tubes, microtiter dishes, and petri plates. Culturing can be carried out at a temperature, pH and oxygen content appropriate for a recombinant cell. Such culturing conditions are within the expertise of one of ordinary skill in the art. A preferred means of producing the polypeptides is in a transgenic plant, preferably a transgenic cereal plant.

Polynucleotides and Genes

The present invention refers to various polynucleotides. As used herein, a "polynucleotide" or "nucleic acid" or "nucleic acid molecule" means a polymer of nucleotides, which may be DNA or RNA or a combination thereof, and includes mRNA, cRNA, cDNA, tRNA, siRNA, shRNA and hpRNA. It may be DNA or RNA of cellular, genomic or synthetic origin, for example made on an automated synthesizer, and may be combined with carbohydrate, lipids, protein or other materials, labelled with fluorescent or other groups, or attached to a solid support to perform a particular activity defined herein, or comprise one or more modified nucleotides not found in nature, well known to those skilled in the art. The polymer may be single-stranded, essentially double-stranded or partly double-stranded. An example of a partly-double stranded RNA molecule is a hairpin RNA (hpRNA), short hairpin RNA (shRNA) or self-complementary RNA which include a double stranded stem formed by basepairing between a nucleotide sequence and its complement and a loop sequence which covalently joins the nucleotide sequence and its complement. Basepairing as used herein refers to standard basepairing between nucleotides, including G: U basepairs. "Complementary" means two polynucleotides are capable of basepairing (hybridizing) along part of their lengths, or along the full length of one or both. A "hybridized polynucleotide" means the polynucleotide is actually basepaired to its complement. The term "polynucleotide" is used interchangeably herein with the term "nucleic acid".

By "isolated polynucleotide" we mean a polynucleotide which has generally been separated from the polynucleotide sequences with which it is associated or linked in its native

state. Preferably, the isolated polynucleotide is at least 90% free from other components with which it is naturally associated.

The present invention involves modification of gene activity and the construction and use of chimeric genes. As used herein, the term "gene" includes any deoxyribonucleotide sequence which includes a protein coding region or which is transcribed in a cell but not translated, as well as associated non-coding and regulatory regions. Such associated regions are typically located adjacent to the coding region or the transcribed region on both the 5' and 3' ends for a distance of about 2 kb on either side. In this regard, the gene may include control signals such as promoters, enhancers, termination and/or polyadenylation signals that are naturally associated with a given gene, or heterologous control signals in which case the gene is referred to as a "chimeric gene". The sequences which are located 5' of the coding region and which are present on the mRNA are referred to as 5' non-translated sequences. The sequences which are located 3' or downstream of the coding region and which are present on the mRNA are referred to as 3' non-translated sequences. The term "gene" encompasses both cDNA and genomic forms of a gene.

A "Lr34 gene" as used herein refers to a nucleotide sequence which is homologous to the isolated Lr34 gene (SEQ ID NO:3) or Lr34 cDNA (SEQ ID NO:2) described herein, which encodes a protein that confers resistance to a pathogen, preferably a fungal pathogen, on a plant, preferably a cereal plant and more preferably a wheat plant. Preferably, the protein confers resistance to more than one fungal pathogen. Lr34 genes include the naturally occurring alleles or variants existing in cereals such as wheat, including those encoded by the D genomes of hexaploid wheat and its D genome diploid progenitors or relatives, as well as non-naturally occurring variants which may be produced by those skilled in the art of gene modification. Nucleic acid molecules having the nucleotide sequence shown herein as SEQ ID NO:2 (cDNA) or SEQ ID NO:3 (genomic sequence), encoding a protein with amino acid sequence SEQ ID NO:1, are examples of an Lr34 gene. In a preferred embodiment, a Lr34 gene refers to a nucleic acid molecule comprising nucleotides having a sequence having at least 90% identity to SEQ ID NO:2.

A genomic form or clone of a gene containing the transcribed region may be interrupted with non-coding sequences termed "introns" or "intervening regions" or "intervening sequences." An "intron" as used herein is a segment of a gene which is transcribed as part of a primary RNA transcript but is not present in the mature mRNA molecule. Introns are removed or "spliced out" from the nuclear or primary transcript; introns therefore are absent in the messenger RNA (mRNA). Introns may contain regulatory elements such as enhancers. "Exons" as used herein refer to the DNA regions corresponding to the RNA sequences which are present in the mature mRNA or the mature RNA molecule in cases where the RNA molecule is not translated. An mRNA functions during translation to specify the sequence or order of amino acids in a nascent polypeptide. The term "gene" includes a synthetic or fusion molecule encoding all or part of the proteins of the invention described herein and a complementary nucleotide sequence to any one of the above. A gene may be introduced into an appropriate vector for extrachromosomal maintenance in a cell or for integration into the host genome.

As used herein, a "chimeric gene" refers to any gene that is not a native gene in its native location. Typically, a chimeric gene comprises regulatory and transcribed or protein coding sequences that are not found together in nature. Accordingly,

15

a chimeric gene may comprise regulatory sequences and coding sequences that are derived from different sources, or regulatory sequences and coding sequences derived from the same source, but arranged in a manner different than that found in nature. The term "endogenous" is used herein to refer to a substance that is normally present or produced in an unmodified plant at the same developmental stage as the plant under investigation. An "endogenous gene" refers to a native gene in its natural location in the genome of an organism. As used herein, "recombinant nucleic acid molecule", "recombinant polynucleotide" or variations thereof refer to a nucleic acid molecule which has been constructed or modified by recombinant DNA technology. The terms "foreign polynucleotide" or "exogenous polynucleotide" or "heterologous polynucleotide" and the like refer to any nucleic acid which is introduced into the genome of a cell by experimental manipulations. For example, the present inventors have identified the Lr34 homeolog on wheat chromosome 7B (see SEQ ID NO's 63 and 64). The skilled person can use this information to mutant the Lr34 gene homeolog in durum wheat such that it encodes a protein of the invention which lacks a phenylalanine residue or any amino acid at a position corresponding to amino acid number 546 of SEQ ID NO:4, and has an amino acid other than a tyrosine residue at a position corresponding to amino acid number 634 of SEQ ID NO:4. Such a mutated gene, and the encoded mRNA, would be considered as an "exogenous" polynucleotide of the invention.

Foreign or exogenous genes may be genes that are inserted into a non-native organism, native genes introduced into a new location within the native host, or chimeric genes. A "transgene" is a gene that has been introduced into the genome by a transformation procedure. The term "genetically modified" includes introducing genes into cells by transformation or transduction, mutating genes in cells and altering or modulating the regulation of a gene in a cell or organisms to which these acts have been done or their progeny.

Furthermore, the term "exogenous" in the context of a polynucleotide (nucleic acid) refers to the polynucleotide when present in a cell, or in a cell-free expression system, in an altered amount compared to its native state. In one embodiment, the cell is a cell that does not naturally comprise the polynucleotide. However, the cell may be a cell which comprises a non-endogenous polynucleotide resulting in an altered amount of production of the encoded polypeptide. An exogenous polynucleotide of the invention includes polynucleotides which have not been separated from other components of the transgenic (recombinant) cell, or cell-free expression system, in which it is present, and polynucleotides produced in such cells or cell-free systems which are subsequently purified away from at least some other components. The exogenous polynucleotide (nucleic acid) can be a contiguous stretch of nucleotides existing in nature, or comprise two or more contiguous stretches of nucleotides from different sources (naturally occurring and/or synthetic) joined to form a single polynucleotide. Typically such chimeric polynucleotides comprise at least an open reading frame encoding a polypeptide of the invention operably linked to a promoter suitable of driving transcription of the open reading frame in a cell of interest.

The % identity of a polynucleotide is determined by GAP (Needleman and Wunsch, 1970) analysis (GCG program) with a gap creation penalty=5, and a gap extension penalty=0.3. The query sequence is at least 450 nucleotides in length, and the GAP analysis aligns the two sequences over a region of at least 450 nucleotides. Preferably, the query sequence is at least 1,500 nucleotides in length, and the GAP analysis aligns the two sequences over a region of at least

16

1,500 nucleotides. Even more preferably, the query sequence is at least 3,000 nucleotides in length and the GAP analysis aligns the two sequences over a region of at least 3,000 nucleotides. Even more preferably, the GAP analysis aligns two sequences over their entire length.

With regard to the defined polynucleotides, it will be appreciated that % identity figures higher than those provided above will encompass preferred embodiments. Thus, where applicable, in light of the minimum % identity figures, it is preferred that the polynucleotide comprises a polynucleotide sequence which is at least 60%, more preferably at least 65%, more preferably at least 70%, more preferably at least 75%, more preferably at least 80%, more preferably at least 85%, more preferably at least 90%, more preferably at least 91%, more preferably at least 92%, more preferably at least 93%, more preferably at least 94%, more preferably at least 95%, more preferably at least 96%, more preferably at least 97%, more preferably at least 98%, more preferably at least 99%, more preferably at least 99.1%, more preferably at least 99.2%, more preferably at least 99.3%, more preferably at least 99.4%, more preferably at least 99.5%, more preferably at least 99.6%, more preferably at least 99.7%, more preferably at least 99.8%, and even more preferably at least 99.9% identical to the relevant nominated SEQ ID NO.

In a preferred embodiment, the polynucleotide of the invention is not a sequence of nucleotides as provided in any one of SEQ ID NO's 7 to 11.

In a further embodiment, the present invention relates to polynucleotides which are substantially identical to those specifically described herein. As used herein, with reference to a polynucleotide the term "substantially identical" means the substitution of one or a few (for example 2, 3, or 4) nucleotides whilst maintaining at least one activity of the native protein encoded by the polynucleotide. In addition, this term includes the addition or deletion of nucleotides which results in the increase or decrease in size of the encoded native protein by one or a few (for example 2, 3, or 4) amino acids whilst maintaining at least one activity of the native protein encoded by the polynucleotide.

The present invention refers to use of oligonucleotides. As used herein, "oligonucleotides" are polynucleotides up to 50 nucleotides in length. The minimum size of such oligonucleotides is the size required for the formation of a stable hybrid between an oligonucleotide and a complementary sequence on a nucleic acid molecule of the present invention. They can be RNA, DNA, or combinations or derivatives of either. Oligonucleotides are typically relatively short single stranded molecules of 10 to 30 nucleotides, commonly 15-25 nucleotides in length. When used as a probe or as a primer in an amplification reaction, the minimum size of such an oligonucleotide is the size required for the formation of a stable hybrid between the oligonucleotide and a complementary sequence on a target nucleic acid molecule. Preferably, the oligonucleotides are at least 15 nucleotides, more preferably at least 18 nucleotides, more preferably at least 19 nucleotides, more preferably at least 20 nucleotides, even more preferably at least 25 nucleotides in length. Oligonucleotides of the present invention used as a probe are typically conjugated with a label such as a radioisotope, an enzyme, biotin, a fluorescent molecule or a chemiluminescent molecule.

The present invention includes oligonucleotides that can be used as, for example, probes to identify nucleic acid molecules, or primers to produce nucleic acid molecules. Probes and/or primers can be used to clone homologues of the polynucleotides of the invention from other species. Furthermore, hybridization techniques known in the art can also be used to screen genomic or cDNA libraries for such homologues.

Polynucleotides and oligonucleotides of the present invention include those which hybridize under stringent conditions to a sequence provided as SEQ ID NO's: 2 and/or 3. As used herein, stringent conditions are those that (1) employ low ionic strength and high temperature for washing, for example, 0.015 M NaCl/0.0015 M sodium citrate/0.1% NaDodSO₄ at 50° C.; (2) employ during hybridisation a denaturing agent such as formamide, for example, 50% (vol/vol) formamide with 0.1% bovine serum albumin, 0.1% Ficoll, 0.1% polyvinylpyrrolidone, 50 mM sodium phosphate buffer at pH 6.5 with 750 mM NaCl, 75 mM sodium citrate at 42° C.; or (3) employ 50% formamide, 5×SSC (0.75 M NaCl, 0.075 M sodium citrate), 50 mM sodium phosphate (pH 6.8), 0.1% sodium pyrophosphate, 5×Denhardt's solution, sonicated salmon sperm DNA (50 g/ml), 0.1% SDS and 10% dextran sulfate at 42° C. in 0.2×SSC and 0.1% SDS.

Polynucleotides of the present invention may possess, when compared to naturally occurring molecules, one or more mutations which are deletions, insertions, or substitutions of nucleotide residues. Mutants can be either naturally occurring (that is to say, isolated from a natural source) or synthetic (for example, by performing site-directed mutagenesis on the nucleic acid). A variant of a polynucleotide or an oligonucleotide of the invention includes molecules of varying sizes of, and/or are capable of hybridising to, the wheat genome close to that of the reference polynucleotide or oligonucleotide molecules defined herein. For example, variants may comprise additional nucleotides (such as 1, 2, 3, 4, or more), or less nucleotides as long as they still hybridise to the target region. Furthermore, a few nucleotides may be substituted without influencing the ability of the oligonucleotide to hybridise to the target region. In addition, variants may readily be designed which hybridise close to, for example to within 50 nucleotides, the region of the plant genome where the specific oligonucleotides defined herein hybridise. In particular, this includes polynucleotides which encode the same polypeptide or amino acid sequence but which vary in nucleotide sequence by redundancy of the genetic code. The terms "polynucleotide variant" and "variant" also include naturally occurring allelic variants.

Nucleic Acid Constructs

The present invention includes nucleic acid constructs comprising the polynucleotides of the invention, and vectors and host cells containing these, methods of their production and use, and uses thereof. The present invention refers to elements which are operably connected or linked. "Operably connected" or "operably linked" and the like refer to a linkage of polynucleotide elements in a functional relationship. Typically, operably connected nucleic acid sequences are contiguously linked and, where necessary to join two protein coding regions, contiguous and in reading frame. A coding sequence is "operably connected to" another coding sequence when RNA polymerase will transcribe the two coding sequences into a single RNA, which if translated is then translated into a single polypeptide having amino acids derived from both coding sequences. The coding sequences need not be contiguous to one another so long as the expressed sequences are ultimately processed to produce the desired protein.

As used herein, the term "cis-acting sequence", "cis-acting element" or "cis-regulatory region" or "regulatory region" or similar term shall be taken to mean any sequence of nucleotides, which when positioned appropriately and connected relative to an expressible genetic sequence, is capable of regulating, at least in part, the expression of the genetic sequence. Those skilled in the art will be aware that a cis-regulatory region may be capable of activating, silencing, enhancing, repressing or otherwise altering the level of

expression and/or cell-type-specificity and/or developmental specificity of a gene sequence at the transcriptional or post-transcriptional level. In preferred embodiments of the present invention, the cis-acting sequence is an activator sequence that enhances or stimulates the expression of an expressible genetic sequence.

"Operably connecting" a promoter or enhancer element to a transcribable polynucleotide means placing the transcribable polynucleotide (e.g., protein-encoding polynucleotide or other transcript) under the regulatory control of a promoter, which then controls the transcription of that polynucleotide. In the construction of heterologous promoter/structural gene combinations, it is generally preferred to position a promoter or variant thereof at a distance from the transcription start site of the transcribable polynucleotide which is approximately the same as the distance between that promoter and the protein coding region it controls in its natural setting; i.e., the gene from which the promoter is derived. As is known in the art, some variation in this distance can be accommodated without loss of function. Similarly, the preferred positioning of a regulatory sequence element (e.g., an operator, enhancer etc) with respect to a transcribable polynucleotide to be placed under its control is defined by the positioning of the element in its natural setting; i.e., the genes from which it is derived.

"Promoter" or "promoter sequence" as used herein refers to a region of a gene, generally upstream (5') of the RNA encoding region, which controls the initiation and level of transcription in the cell of interest. A "promoter" includes the transcriptional regulatory sequences of a classical genomic gene, such as a TATA box and CCAAT box sequences, as well as additional regulatory elements (i.e., upstream activating sequences, enhancers and silencers) that alter gene expression in response to developmental and/or environmental stimuli, or in a tissue-specific or cell-type-specific manner. A promoter is usually, but not necessarily (for example, some PolIII promoters), positioned upstream of a structural gene, the expression of which it regulates. Furthermore, the regulatory elements comprising a promoter are usually positioned within 2 kb of the start site of transcription of the gene. Promoters may contain additional specific regulatory elements, located more distal to the start site to further enhance expression in a cell, and/or to alter the timing or inducibility of expression of a structural gene to which it is operably connected.

"Constitutive promoter" refers to a promoter that directs expression of an operably linked transcribed sequence in many or all tissues of an organism such as a plant. The term constitutive as used herein does not necessarily indicate that a gene is expressed at the same level in all cell types, but that the gene is expressed in a wide range of cell types, although some variation in level is often detectable. "Selective expression" as used herein refers to expression almost exclusively in specific organs of, for example, the plant, such as, for example, endosperm, embryo, leaves, fruit, tubers or root. In a preferred embodiment, a promoter is expressed selectively or preferentially in leaves and/or stems of a plant, preferably a cereal plant. Selective expression may therefore be contrasted with constitutive expression, which refers to expression in many or all tissues of a plant under most or all of the conditions experienced by the plant.

Selective expression may also result in compartmentation of the products of gene expression in specific plant tissues, organs or developmental stages. Compartmentation in specific subcellular locations such as the plastid, cytosol, vacuole, or apoplastic space may be achieved by the inclusion in the structure of the gene product of appropriate signals, eg. a

signal peptide, for transport to the required cellular compartment, or in the case of the semi-autonomous organelles (plastids and mitochondria) by integration of the transgene with appropriate regulatory sequences directly into the organelle genome.

A "tissue-specific promoter" or "organ-specific promoter" is a promoter that is preferentially expressed in one tissue or organ relative to many other tissues or organs, preferably most if not all other tissues or organs in, for example, a plant. Typically, the promoter is expressed at a level 10-fold higher in the specific tissue or organ than in other tissues or organs.

The promoters contemplated by the present invention may be native to the host plant to be transformed or may be derived from an alternative source, where the region is functional in the host plant. Other sources include the *Agrobacterium* T-DNA genes, such as the promoters of genes for the biosynthesis of nopaline, octapine, mannopine, or other opine promoters, tissue specific promoters (see, e.g., U.S. Pat. No. 5,459,252 and WO 91/13992); promoters from viruses (including host specific viruses), or partially or wholly synthetic promoters. Numerous promoters that are functional in mono- and dicotyledonous plants are well known in the art (see, for example, Greve, 1983; Salomon et al., 1984; Garfinkel et al., 1983; Barker et al., 1983); including various promoters isolated from plants and viruses such as the cauliflower mosaic virus promoter (CaMV 35S, 19S). Non-limiting methods for assessing promoter activity are disclosed by Medberry et al. (1992, 1993), Sambrook et al. (1989, supra) and U.S. Pat. No. 5,164,316.

Alternatively or additionally, the promoter may be an inducible promoter or a developmentally regulated promoter which is capable of driving expression of the introduced polynucleotide at an appropriate developmental stage of the, for example, plant. Other cis-acting sequences which may be employed include transcriptional and/or translational enhancers. Enhancer regions are well known to persons skilled in the art, and can include an ATG translational initiation codon and adjacent sequences. When included, the initiation codon should be in phase with the reading frame of the coding sequence relating to the foreign or exogenous polynucleotide to ensure translation of the entire sequence if it is to be translated. Translational initiation regions may be provided from the source of the transcriptional initiation region, or from a foreign or exogenous polynucleotide. The sequence can also be derived from the source of the promoter selected to drive transcription, and can be specifically modified so as to increase translation of the mRNA.

In an embodiment, the promoter is at least capable of expressing the polypeptide in leaves of the plant, particularly adult leaves. Examples of leaf-specific promoters which can be used include those described in Yamamoto et al. (1994 and 1997), Kwon et al. (1994), Gotor et al. (1993), Orozco et al. (1993), Matsuoka et al. (1993) and Stockhaus et al. (1987 and 1989).

The nucleic acid construct of the present invention may comprise a 3' non-translated sequence from about 50 to 1,000 nucleotide base pairs which may include a transcription termination sequence. A 3' non-translated sequence may contain a transcription termination signal which may or may not include a polyadenylation signal and any other regulatory signals capable of effecting mRNA processing. A polyadenylation signal functions for addition of polyadenylic acid tracts to the 3' end of a mRNA precursor. Polyadenylation signals are commonly recognized by the presence of homology to the canonical form 5' AATAAA-3' although variations are not uncommon. Transcription termination sequences which do not include a polyadenylation signal include terminators for

Poll or PolIII RNA polymerase which comprise a run of four or more thymidines. Examples of suitable 3' non-translated sequences are the 3' transcribed non-translated regions containing a polyadenylation signal from an octopine synthase (ocs) gene or nopaline synthase (nos) gene of *Agrobacterium tumefaciens* (Bevan et al., 1983). Suitable 3' non-translated sequences may also be derived from plant genes such as the ribulose-1,5-bisphosphate carboxylase (ssRUBISCO) gene, although other 3' elements known to those of skill in the art can also be employed.

As the DNA sequence inserted between the transcription initiation site and the start of the coding sequence, i.e., the untranslated 5' leader sequence (5'UTR), can influence gene expression if it is translated as well as transcribed, one can also employ a particular leader sequence. Suitable leader sequences include those that comprise sequences selected to direct optimum expression of the foreign or endogenous DNA sequence. For example, such leader sequences include a preferred consensus sequence which can increase or maintain mRNA stability and prevent inappropriate initiation of translation as for example described by Joshi (1987).

Vectors

The present invention includes use of vectors for manipulation or transfer of genetic constructs. By "chimeric vector" is meant a nucleic acid molecule, preferably a DNA molecule derived, for example, from a plasmid, bacteriophage, or plant virus, into which a nucleic acid sequence may be inserted or cloned. A vector preferably is double-stranded DNA and contains one or more unique restriction sites and may be capable of autonomous replication in a defined host cell including a target cell or tissue or a progenitor cell or tissue thereof, or capable of integration into the genome of the defined host such that the cloned sequence is reproducible. Accordingly, the vector may be an autonomously replicating vector, i.e., a vector that exists as an extrachromosomal entity, the replication of which is independent of chromosomal replication, e.g., a linear or closed circular plasmid, an extrachromosomal element, a minichromosome, or an artificial chromosome. The vector may contain any means for assuring self-replication. Alternatively, the vector may be one which, when introduced into a cell, is integrated into the genome of the recipient cell and replicated together with the chromosome(s) into which it has been integrated. A vector system may comprise a single vector or plasmid, two or more vectors or plasmids, which together contain the total DNA to be introduced into the genome of the host cell, or a transposon. The choice of the vector will typically depend on the compatibility of the vector with the cell into which the vector is to be introduced. The vector may also include a selection marker such as an antibiotic resistance gene, a herbicide resistance gene or other gene that can be used for selection of suitable transformants. Examples of such genes are well known to those of skill in the art.

The nucleic acid construct of the invention can be introduced into a vector, such as a plasmid. Plasmid vectors typically include additional nucleic acid sequences that provide for easy selection, amplification, and transformation of the expression cassette in prokaryotic and eukaryotic cells, e.g., pUC-derived vectors, pSK-derived vectors, pGEM-derived vectors, pSP-derived vectors, pBS-derived vectors, or binary vectors containing one or more T-DNA regions. Additional nucleic acid sequences include origins of replication to provide for autonomous replication of the vector, selectable marker genes, preferably encoding antibiotic or herbicide resistance, unique multiple cloning sites providing for multiple sites to insert nucleic acid sequences or genes encoded in

the nucleic acid construct, and sequences that enhance transformation of prokaryotic and eukaryotic (especially plant) cells.

By "marker gene" is meant a gene that imparts a distinct phenotype to cells expressing the marker gene and thus allows such transformed cells to be distinguished from cells that do not have the marker. A selectable marker gene confers a trait for which one can "select" based on resistance to a selective agent (e.g., a herbicide, antibiotic, radiation, heat, or other treatment damaging to untransformed cells). A screenable marker gene (or reporter gene) confers a trait that one can identify through observation or testing, i.e., by "screening" (e.g., β -glucuronidase, luciferase, GFP or other enzyme activity not present in untransformed cells). The marker gene and the nucleotide sequence of interest do not have to be linked.

To facilitate identification of transformants, the nucleic acid construct desirably comprises a selectable or screenable marker gene as, or in addition to, the foreign or exogenous polynucleotide. The actual choice of a marker is not crucial as long as it is functional (i.e., selective) in combination with the plant cells of choice. The marker gene and the foreign or exogenous polynucleotide of interest do not have to be linked, since co-transformation of unlinked genes as, for example, described in U.S. Pat. No. 4,399,216 is also an efficient process in plant transformation.

Examples of bacterial selectable markers are markers that confer antibiotic resistance such as ampicillin, erythromycin, chloramphenicol or tetracycline resistance, preferably kanamycin resistance. Exemplary selectable markers for selection of plant transformants include, but are not limited to, a hyg gene which encodes hygromycin B resistance; a neomycin phosphotransferase (nptII) gene conferring resistance to kanamycin, paromomycin, G418; a glutathione-S-transferase gene from rat liver conferring resistance to glutathione derived herbicides as, for example, described in EP 256223; a glutamine synthetase gene conferring, upon overexpression, resistance to glutamine synthetase inhibitors such as phosphinothricin as, for example, described in WO 87/05327, an acetyltransferase gene from *Streptomyces viridochromogenes* conferring resistance to the selective agent phosphinothricin as, for example, described in EP 275957, a gene encoding a 5-enolshikimate-3-phosphate synthase (EPSPS) conferring tolerance to N-phosphonomethylglycine as, for example, described by Hinchey et al. (1988), a bar gene conferring resistance against bialaphos as, for example, described in WO91/02071; a nitrilase gene such as bxn from *Klebsiella ozaenae* which confers resistance to bromoxynil (Stalker et al., 1988); a dihydrofolate reductase (DHFR) gene conferring resistance to methotrexate (Thillet et al., 1988); a mutant acetolactate synthase gene (ALS), which confers resistance to imidazolinone, sulfonylurea or other ALS-inhibiting chemicals (EP 154,204); a mutated anthranilate synthase gene that confers resistance to 5-methyl tryptophan; or a dalapon dehalogenase gene that confers resistance to the herbicide.

Preferred screenable markers include, but are not limited to, a uidA gene encoding a β -glucuronidase (GUS) enzyme for which various chromogenic substrates are known, a β -galactosidase gene encoding an enzyme for which chromogenic substrates are known, an aequorin gene (Prasher et al., 1985), which may be employed in calcium-sensitive bioluminescence detection; a green fluorescent protein gene (Niedz et al., 1995) or derivatives thereof; a luciferase (luc) gene (Ow et al., 1986), which allows for bioluminescence detection, and others known in the art. By "reporter molecule" as used in the present specification is meant a molecule that, by its chemical

nature, provides an analytically identifiable signal that facilitates determination of promoter activity by reference to protein product.

Preferably, the nucleic acid construct is stably incorporated into the genome of, for example, the plant. Accordingly, the nucleic acid comprises appropriate elements which allow the molecule to be incorporated into the genome, or the construct is placed in an appropriate vector which can be incorporated into a chromosome of a plant cell.

One embodiment of the present invention includes a recombinant vector, which includes at least one polynucleotide molecule of the present invention, inserted into any vector capable of delivering the nucleic acid molecule into a host cell. Such a vector contains heterologous nucleic acid sequences, that is nucleic acid sequences that are not naturally found adjacent to nucleic acid molecules of the present invention and that preferably are derived from a species other than the species from which the nucleic acid molecule(s) are derived. The vector can be either RNA or DNA, either prokaryotic or eukaryotic, and typically is a virus or a plasmid.

A number of vectors suitable for stable transfection of plant cells or for the establishment of transgenic plants have been described in, e.g., Pouwels et al., Cloning

Vectors: A Laboratory Manual, 1985, supp. 1987; Weissbach and Weissbach, Methods for Plant Molecular Biology, Academic Press, 1989; and Gelvin et al., Plant Molecular Biology Manual, Kluwer Academic Publishers, 1990. Typically, plant expression vectors include, for example, one or more cloned plant genes under the transcriptional control of 5' and 3' regulatory sequences and a dominant selectable marker. Such plant expression vectors also can contain a promoter regulatory region (e.g., a regulatory region controlling inducible or constitutive, environmentally- or developmentally-regulated, or cell- or tissue-specific expression), a transcription initiation start site, a ribosome binding site, an RNA processing signal, a transcription termination site, and/or a polyadenylation signal.

The level of a protein, for example Lr34 protein, may be modulated by increasing the level of expression of a nucleotide sequence that codes for the protein in a plant cell, or decreasing the level of expression of a gene encoding the protein in the plant, leading to modified pathogen resistance. The level of expression of a gene may be modulated by altering the copy number per cell, for example by introducing a synthetic genetic construct comprising the coding sequence and a transcriptional control element that is operably connected thereto and that is functional in the cell. A plurality of transformants may be selected and screened for those with a favourable level and/or specificity of transgene expression arising from influences of endogenous sequences in the vicinity of the transgene integration site. A favourable level and pattern of transgene expression is one which results in a substantial modification of pathogen resistance or other phenotype. Alternatively, a population of mutagenized seed or a population of plants from a breeding program may be screened for individual lines with altered pathogen resistance or other phenotype associated with pathogen resistance.

Recombinant Cells

Another embodiment of the present invention includes a recombinant cell comprising a host cell transformed with one or more recombinant molecules of the present invention, or progeny cells thereof. Transformation of a nucleic acid molecule into a cell can be accomplished by any method by which a nucleic acid molecule can be inserted into the cell. Transformation techniques include, but are not limited to, transfection, electroporation, microinjection, lipofection, adsorption,

and protoplast fusion. A recombinant cell may remain unicellular or may grow into a tissue, organ or a multicellular organism. Transformed nucleic acid molecules of the present invention can remain extrachromosomal or can integrate into one or more sites within a chromosome of the transformed (i.e., recombinant) cell in such a manner that their ability to be expressed is retained. Preferred host cells are plant cells, more preferably cells of a cereal plant, more preferably barley or wheat cells, and even more preferably a wheat cell.

Transgenic Plants

The term "plant" as used herein as a noun refers to whole plants and refers to any member of the Kingdom Plantae, but as used as an adjective refers to any substance which is present in, obtained from, derived from, or related to a plant, such as for example, plant organs (e.g. leaves, stems, roots, flowers), single cells (e.g. pollen), seeds, plant cells and the like. Plantlets and germinated seeds from which roots and shoots have emerged are also included within the meaning of "plant". The term "plant parts" as used herein refers to one or more plant tissues or organs which are obtained from a plant and which comprises genomic DNA of the plant. Plant parts include vegetative structures (for example, leaves, stems), roots, floral organs/structures, seed (including embryo, cotyledons, and seed coat), plant tissue (for example, vascular tissue, ground tissue, and the like), cells and progeny of the same. The term "plant cell" as used herein refers to a cell obtained from a plant or in a plant and includes protoplasts or other cells derived from plants, gamete-producing cells, and cells which regenerate into whole plants. Plant cells may be cells in culture. By "plant tissue" is meant differentiated tissue in a plant or obtained from a plant ("explant") or undifferentiated tissue derived from immature or mature embryos, seeds, roots, shoots, fruits, tubers, pollen, tumor tissue, such as crown galls, and various forms of aggregations of plant cells in culture, such as calli. Exemplary plant tissues in or from seeds are cotyledon, embryo and embryo axis. The invention accordingly includes plants and plant parts and products comprising these, particularly seed comprising modified oil composition.

As used herein, the term "seed" refers to "mature seed" of a plant, which is either ready for harvesting or has been harvested from the plant, such as is typically harvested commercially in the field, or as "developing seed" which occurs in a plant after fertilization and prior to seed dormancy being established and before harvest.

A "transgenic plant" as used herein refers to a plant that contains a nucleic acid construct not found in a wild-type plant of the same species, variety or cultivar. That is, transgenic plants (transformed plants) contain genetic material (a transgene) that they did not contain prior to the transformation. The transgene may include genetic sequences obtained from or derived from a plant cell, or another plant cell, or a non-plant source, or a synthetic sequence. Typically, the transgene has been introduced into the plant by human manipulation such as, for example, by transformation but any method can be used as one of skill in the art recognizes. The genetic material is preferably stably integrated into the genome of the plant. The introduced genetic material may comprise sequences that naturally occur in the same species but in a rearranged order or in a different arrangement of elements, for example an antisense sequence. Plants containing such sequences are included herein in "transgenic plants". A "non-transgenic plant" is one which has not been genetically modified by the introduction of genetic material by recombinant DNA techniques. In a preferred embodiment, the transgenic plants are homozygous for each and every gene

that has been introduced (transgene) so that their progeny do not segregate for the desired phenotype.

As used herein, the term "compared to an isogenic plant" refers to a plant which is isogenic relative to the transgenic plant but without the transgene of interest. Preferably, the corresponding non-transgenic plant is of the same cultivar or variety as the progenitor of the transgenic plant of interest, or a sibling plant line which lacks the construct, often termed a "segregant", or a plant of the same cultivar or variety transformed with an "empty vector" construct, and may be a non-transgenic plant. "Wild type", as used herein, refers to a cell, tissue or plant that has not been modified according to the invention. Wild-type cells, tissue or plants may be used as controls to compare levels of expression of an exogenous nucleic acid or the extent and nature of trait modification with cells, tissue or plants modified as described herein.

Transgenic plants, as defined in the context of the present invention include progeny of the plants which have been genetically modified using recombinant techniques, wherein the progeny comprise the transgene of interest. Such progeny may be obtained by self-fertilization of the primary transgenic plant or by crossing such plants with another plant of the same species. This would generally be to modulate the production of at least one protein defined herein in the desired plant or plant organ. Transgenic plant parts include all parts and cells of said plants comprising the transgene such as, for example, cultured tissues, callus and protoplasts.

Plants contemplated for use in the practice of the present invention include both monocotyledons and dicotyledons. Target plants include, but are not limited to, the following: cereals (for example, wheat, barley, rye, oats, rice, maize, sorghum and related crops); beet (sugar beet and fodder beet); pomes, stone fruit and soft fruit (apples, pears, plums, peaches, almonds, cherries, strawberries, raspberries and black-berries); leguminous plants (beans, lentils, peas, soybeans); oil plants (rape or other Brassicas, mustard, poppy, olives, sunflowers, safflower, flax, coconut, castor oil plants, cocoa beans, groundnuts); cucumber plants (marrows, cucumbers, melons); fibre plants (cotton, flax, hemp, jute); citrus fruit (oranges, lemons, grapefruit, mandarins); vegetables (spinach, lettuce, asparagus, cabbages, carrots, onions, tomatoes, potatoes, paprika); lauraceae (avocados, cinnamon, camphor); or plants such as maize, tobacco, nuts, coffee, sugar cane, tea, vines, hops, turf, bananas and natural rubber plants, as well as ornamentals (flowers, shrubs, broad-leaved trees and evergreens, such as conifers). Preferably, the plant is a cereal plant, more preferably wheat, rice, maize, triticale, oats or barley, even more preferably wheat.

As used herein, the term "wheat" refers to any species of the Genus *Triticum*, including progenitors thereof, as well as progeny thereof produced by crosses with other species. Wheat includes "hexaploid wheat" which has genome organization of AABBDD, comprised of 42 chromosomes, and "tetraploid wheat" which has genome organization of AABB, comprised of 28 chromosomes. Hexaploid wheat includes *T. aestivum*, *T. spelta*, *T. macha*, *T. compactum*, *T. sphaerococcum*, *T. vavilovii*, and interspecies cross thereof. A preferred species of hexaploid wheat is *T. aestivum* ssp. *aestivum* (also termed "breadwheat"). Tetraploid wheat includes *T. durum* (also referred to herein as durum wheat or *Triticum turgidum* ssp. *durum*), *T. dicoccoides*, *T. dicoccum*, *T. polonicum*, and interspecies cross thereof. In addition, the term "wheat" includes potential progenitors of hexaploid or tetraploid *Triticum* sp. such as *T. urartu*, *T. monococcum* or *T. boeoticum* for the A genome, *Aegilops speltoides* for the B genome, and *T. tauschii* (also known as *Aegilops squamosa* or *Aegilops tauschii*) for the D genome. Particularly preferred progenitors are

those of the A genome, even more preferably the A genome progenitor is *T. monococcum*. A wheat cultivar for use in the present invention may belong to, but is not limited to, any of the above-listed species. Also encompassed are plants that are produced by conventional techniques using *Triticum* sp. as a parent in a sexual cross with a non-*Triticum* species (such as rye [*Secale cereale*]), including but not limited to *Triticale*.

As used herein, the term "barley" refers to any species of the Genus *Hordeum*, including progenitors thereof, as well as progeny thereof produced by crosses with other species. It is preferred that the plant is of a *Hordeum* species which is commercially cultivated such as, for example, a strain or cultivar or variety of *Hordeum vulgare* or suitable for commercial production of grain.

Transgenic plants, as defined in the context of the present invention include plants (as well as parts and cells of said plants) and their progeny which have been genetically modified using recombinant techniques to cause production of at least one polypeptide of the present invention in the desired plant or plant organ. Transgenic plants can be produced using techniques known in the art, such as those generally described in A. Slater et al., *Plant Biotechnology—The Genetic Manipulation of Plants*, Oxford University Press (2003), and P. Christou and H. Klee, *Handbook of Plant Biotechnology*, John Wiley and Sons (2004).

In a preferred embodiment, the transgenic plants are homozygous for each and every gene that has been introduced (transgene) so that their progeny do not segregate for the desired phenotype. The transgenic plants may also be heterozygous for the introduced transgene(s), such as, for example, in F1 progeny which have been grown from hybrid seed. Such plants may provide advantages such as hybrid vigour, well known in the art.

Four general methods for direct delivery of a gene into cells have been described: (1) chemical methods (Graham et al., 1973); (2) physical methods such as microinjection (Capechi, 1980); electroporation (see, for example, WO 87/06614, U.S. Pat. Nos. 5,472,869, 5,384,253, WO 92/09696 and WO 93/21335); and the gene gun (see, for example, U.S. Pat. No. 4,945,050 and U.S. Pat. No. 5,141,131); (3) viral vectors (Clapp, 1993; Lu et al., 1993; Eglitis et al., 1988); and (4) receptor-mediated mechanisms (Curiel et al., 1992; Wagner et al., 1992).

Acceleration methods that may be used include, for example, microprojectile bombardment and the like. One example of a method for delivering transforming nucleic acid molecules to plant cells is microprojectile bombardment. This method has been reviewed by Yang et al., *Particle Bombardment Technology for Gene Transfer*, Oxford Press, Oxford, England (1994). Non-biological particles (microprojectiles) that may be coated with nucleic acids and delivered into cells by a propelling force. Exemplary particles include those comprised of tungsten, gold, platinum, and the like. A particular advantage of microprojectile bombardment, in addition to it being an effective means of reproducibly transforming monocots, is that neither the isolation of protoplasts, nor the susceptibility of *Agrobacterium* infection are required. A particle delivery system suitable for use with the present invention is the helium acceleration PDS-1000/He gun is available from Bio-Rad Laboratories. For the bombardment, immature embryos or derived target cells such as scutella or calli from immature embryos may be arranged on solid culture medium.

In another alternative embodiment, plastids can be stably transformed. Method disclosed for plastid transformation in higher plants include particle gun delivery of DNA containing a selectable marker and targeting of the DNA to the plastid

genome through homologous recombination (U.S. Pat. No. 5,451,513, U.S. Pat. No. 5,545,818, U.S. Pat. No. 5,877,402, U.S. Pat. No. 5,932,479, and WO 99/05265).

Agrobacterium-mediated transfer is a widely applicable system for introducing genes into plant cells because the DNA can be introduced into whole plant tissues, thereby bypassing the need for regeneration of an intact plant from a protoplast. The use of *Agrobacterium*-mediated plant integrating vectors to introduce DNA into plant cells is well known in the art (see, for example, U.S. Pat. No. 5,177,010, U.S. Pat. No. 5,104,310, U.S. Pat. No. 5,004,863, U.S. Pat. No. 5,159,135). Further, the integration of the T-DNA is a relatively precise process resulting in few rearrangements. The region of DNA to be transferred is defined by the border sequences, and intervening DNA is usually inserted into the plant genome.

Agrobacterium transformation vectors are capable of replication in *E. coli* as well as *Agrobacterium*, allowing for convenient manipulations as described (Klee et al., *Plant DNA Infectious Agents*, Hohn and Schell, (editors), Springer-Verlag, New York, (1985): 179-203). Moreover, technological advances in vectors for *Agrobacterium*-mediated gene transfer have improved the arrangement of genes and restriction sites in the vectors to facilitate construction of vectors capable of expressing various polypeptide coding genes. The vectors described have convenient multi-linker regions flanked by a promoter and a polyadenylation site for direct expression of inserted polypeptide coding genes and are suitable for present purposes. In addition, *Agrobacterium* containing both armed and disarmed Ti genes can be used for the transformations. In those plant varieties where *Agrobacterium*-mediated transformation is efficient, it is the method of choice because of the facile and defined nature of the gene transfer.

A transgenic plant formed using *Agrobacterium* transformation methods typically contains a single genetic locus on one chromosome. Such transgenic plants can be referred to as being hemizygous for the added gene. More preferred is a transgenic plant that is homozygous for the added structural gene; i.e., a transgenic plant that contains two added genes, one gene at the same locus on each chromosome of a chromosome pair. A homozygous transgenic plant can be obtained by sexually mating (selfing) an independent segregant transgenic plant that contains a single added gene, germinating some of the seed produced and analyzing the resulting plants for the gene of interest.

It is also to be understood that two different transgenic plants can also be mated to produce offspring that contain two independently segregating exogenous genes. Selfing of appropriate progeny can produce plants that are homozygous for both exogenous genes. Back-crossing to a parental plant and out-crossing with a non-transgenic plant are also contemplated, as is vegetative propagation. Descriptions of other breeding methods that are commonly used for different traits and crops can be found in Fehr, *Breeding Methods for Cultivar Development*, J. Wilcox (editor) American Society of Agronomy, Madison Wis. (1987).

Transformation of plant protoplasts can be achieved using methods based on calcium phosphate precipitation, polyethylene glycol treatment, electroporation, and combinations of these treatments. Application of these systems to different plant varieties depends upon the ability to regenerate that particular plant strain from protoplasts. Illustrative methods for the regeneration of cereals from protoplasts are described (Fujimura et al., 1985; Toriyama et al., 1986; Abdullah et al., 1986).

Other methods of cell transformation can also be used and include but are not limited to introduction of DNA into plants by direct DNA transfer into pollen, by direct injection of DNA into reproductive organs of a plant, or by direct injection of DNA into the cells of immature embryos followed by the rehydration of desiccated embryos.

The regeneration, development, and cultivation of plants from single plant protoplast transformants or from various transformed explants is well known in the art (Weissbach et al., Methods for Plant Molecular Biology, Academic Press, San Diego, (1988)). This regeneration and growth process typically includes the steps of selection of transformed cells, culturing those individualized cells through the usual stages of embryonic development through the rooted plantlet stage. Transgenic embryos and seeds are similarly regenerated. The resulting transgenic rooted shoots are thereafter planted in an appropriate plant growth medium such as soil.

The development or regeneration of plants containing the foreign, exogenous gene is well known in the art. Preferably, the regenerated plants are self-pollinated to provide homozygous transgenic plants. Otherwise, pollen obtained from the regenerated plants is crossed to seed-grown plants of agronomically important lines. Conversely, pollen from plants of these important lines is used to pollinate regenerated plants. A transgenic plant of the present invention containing a desired exogenous nucleic acid is cultivated using methods well known to one skilled in the art.

Methods for transforming dicots, primarily by use of *Agrobacterium tumefaciens*, and obtaining transgenic plants have been published for cotton (U.S. Pat. No. 5,004,863, U.S. Pat. No. 5,159,135, U.S. Pat. No. 5,518,908); soybean (U.S. Pat. No. 5,569,834, U.S. Pat. No. 5,416,011); *Brassica* (U.S. Pat. No. 5,463,174); peanut (Cheng et al., 1996); and pea (Grant et al., 1995).

Methods for transformation of cereal plants such as wheat and barley for introducing genetic variation into the plant by introduction of an exogenous nucleic acid and for regeneration of plants from protoplasts or immature plant embryos are well known in the art, see for example, CA 2,092,588, AU 61781/94, AU 667939, U.S. Pat. No. 6,100,447, WO 97/048814, U.S. Pat. No. 5,589,617, U.S. Pat. No. 6,541,257, and other methods are set out in WO 99/14314. Preferably, transgenic wheat or barley plants are produced by *Agrobacterium tumefaciens* mediated transformation procedures. Vectors carrying the desired nucleic acid construct may be introduced into regenerable wheat cells of tissue cultured plants or explants, or suitable plant systems such as protoplasts. The regenerable wheat cells are preferably from the scutellum of immature embryos, mature embryos, callus derived from these, or the meristematic tissue.

To confirm the presence of the transgenes in transgenic cells and plants, a polymerase chain reaction (PCR) amplification or Southern blot analysis can be performed using methods known to those skilled in the art. Expression products of the transgenes can be detected in any of a variety of ways, depending upon the nature of the product, and include Western blot and enzyme assay. One particularly useful way to quantitate protein expression and to detect replication in different plant tissues is to use a reporter gene, such as GUS. Once transgenic plants have been obtained, they may be grown to produce plant tissues or parts having the desired phenotype. The plant tissue or plant parts, may be harvested, and/or the seed collected. The seed may serve as a source for growing additional plants with tissues or parts having the desired characteristics.

Marker Assisted Selection

Marker assisted selection is a well recognised method of selecting for heterozygous plants required when backcrossing with a recurrent parent in a classical breeding program. The population of plants in each backcross generation will be heterozygous for the gene of interest normally present in a 1:1 ratio in a backcross population, and the molecular marker can be used to distinguish the two alleles of the gene. By extracting DNA from, for example, young shoots and testing with a specific marker for the introgressed desirable trait, early selection of plants for further backcrossing is made whilst energy and resources are concentrated on fewer plants. To further speed up the backcrossing program, the embryo from immature seeds (25 days post anthesis) may be excised and grown up on nutrient media under sterile conditions, rather than allowing full seed maturity. This process, termed "embryo rescue", used in combination with DNA extraction at the three leaf stage and analysis of at least one Lr34 gene or allele that confers enhanced resistance to pathogens to the plant, allows rapid selection of plants carrying the desired trait, which may be nurtured to maturity in the greenhouse or field for subsequent further backcrossing to the recurrent parent.

Any molecular biological technique known in the art can be used in the methods of the present invention. Such methods include, but are not limited to, the use of nucleic acid amplification, nucleic acid sequencing, nucleic acid hybridization with suitably labeled probes, single-strand conformational analysis (SSCA), denaturing gradient gel electrophoresis (DGGE), heteroduplex analysis (HET), chemical cleavage analysis (CCM), catalytic nucleic acid cleavage or a combination thereof (see, for example, Lemieux, 2000; Langridge et al., 2001). The invention also includes the use of molecular marker techniques to detect polymorphisms linked to alleles of (for example) Lr34 gene which confers enhanced resistance to plant pathogens. Such methods include the detection or analysis of restriction fragment length polymorphisms (RFLP), RAPD, amplified fragment length polymorphisms (AFLP) and microsatellite (simple sequence repeat, SSR) polymorphisms. The closely linked markers can be obtained readily by methods well known in the art, such as Bulk Segregant Analysis, as reviewed by Langridge et al., (2001).

The "polymerase chain reaction" ("PCR") is a reaction in which replicate copies are made of a target polynucleotide using a "pair of primers" or "set of primers" consisting of "upstream" and a "downstream" primer, and a catalyst of polymerization, such as a DNA polymerase, and typically a thermally-stable polymerase enzyme. Methods for PCR are known in the art, and are taught, for example, in "PCR" (M. J. McPherson and S. G. Moller (editors), BIOS Scientific Publishers Ltd, Oxford, (2000)). PCR can be performed on cDNA obtained from reverse transcribing mRNA isolated from plant cells expressing a Lr34 gene or allele which confers enhanced resistance to plants pathogens. However, it will generally be easier if PCR is performed on genomic DNA isolated from a plant.

A primer is an oligonucleotide sequence that is capable of hybridising in a sequence specific fashion to the target sequence and being extended during the PCR. Amplicons or PCR products or PCR fragments or amplification products are extension products that comprise the primer and the newly synthesized copies of the target sequences. Multiplex PCR systems contain multiple sets of primers that result in simultaneous production of more than one amplicon. Primers may be perfectly matched to the target sequence or they may contain internal mismatched bases that can result in the introduction of restriction enzyme or catalytic nucleic acid recognition/cleavage sites in specific target sequences. Primers

may also contain additional sequences and/or contain modified or labelled nucleotides to facilitate capture or detection of amplicons. Repeated cycles of heat denaturation of the DNA, annealing of primers to their complementary sequences and extension of the annealed primers with polymerase result in exponential amplification of the target sequence. The terms target or target sequence or template refer to nucleic acid sequences which are amplified.

Methods for direct sequencing of nucleotide sequences are well known to those skilled in the art and can be found for example in Ausubel et al., (supra) and Sambrook et al., (supra). Sequencing can be carried out by any suitable method, for example, dideoxy sequencing, chemical sequencing or variations thereof. Direct sequencing has the advantage of determining variation in any base pair of a particular sequence.

TILLING

Plants of the invention can be produced using the process known as TILLING (Targeting Induced Local Lesions IN Genomes). In a first step, introduced mutations such as novel single base pair changes are induced in a population of plants by treating seeds (or pollen) with a chemical mutagen, and then advancing plants to a generation where mutations will be stably inherited. DNA is extracted, and seeds are stored from all members of the population to create a resource that can be accessed repeatedly over time.

For a TILLING assay, PCR primers are designed to specifically amplify a single gene target of interest. Specificity is especially important if a target is a member of a gene family or part of a polyploid genome. Next, dye-labeled primers can be used to amplify PCR products from pooled DNA of multiple individuals. These PCR products are denatured and reannealed to allow the formation of mismatched base pairs. Mismatches, or heteroduplexes, represent both naturally occurring single nucleotide polymorphisms (SNPs) (i.e., several plants from the population are likely to carry the same polymorphism) and induced SNPs (i.e., only rare individual plants are likely to display the mutation). After heteroduplex formation, the use of an endonuclease, such as Cel I, that recognizes and cleaves mismatched DNA is the key to discovering novel SNPs within a TILLING population.

Using this approach, many thousands of plants can be screened to identify any individual with a single base change as well as small insertions or deletions (1-30 bp) in any gene or specific region of the genome. Genomic fragments being assayed can range in size anywhere from 0.3 to 1.6 kb. At 8-fold pooling, 1.4 kb fragments (discounting the ends of fragments where SNP detection is problematic due to noise) and 96 lanes per assay, this combination allows up to a million base pairs of genomic DNA to be screened per single assay, making TILLING a high-throughput technique.

TILLING is further described in Slade and Knauf (2005), and Henikoff et al. (2004).

In addition to allowing efficient detection of mutations, high-throughput TILLING technology is ideal for the detection of natural polymorphisms. Therefore, interrogating an unknown homologous DNA by heteroduplexing to a known sequence reveals the number and position of polymorphic sites. Both nucleotide changes and small insertions and deletions are identified, including at least some repeat number polymorphisms. This has been called Ecotilling (Comai et al., 2004).

Each SNP is recorded by its approximate position within a few nucleotides. Thus, each haplotype can be archived based on its mobility. Sequence data can be obtained with a relatively small incremental effort using aliquots of the same amplified DNA that is used for the mismatch-cleavage assay.

The left or right sequencing primer for a single reaction is chosen by its proximity to the polymorphism. Sequencer software performs a multiple alignment and discovers the base change, which in each case confirmed the gel band.

Ecotilling can be performed more cheaply than full sequencing, the method currently used for most SNP discovery. Plates containing arrayed ecotypic DNA can be screened rather than pools of DNA from mutagenized plants. Because detection is on gels with nearly base pair resolution and background patterns are uniform across lanes, bands that are of identical size can be matched, thus discovering and genotyping SNPs in a single step. In this way, ultimate sequencing of the SNP is simple and efficient, made more so by the fact that the aliquots of the same PCR products used for screening can be subjected to DNA sequencing.

Antibodies

The term "antibody" as used in this invention includes polyclonal antibodies, monoclonal antibodies, bispecific antibodies, diabodies, triabodies, heteroconjugate antibodies, chimeric antibodies including intact molecules as well as fragments thereof, such as Fab, F(ab')₂, and Fv which are capable of binding the epitopic determinant, and other antibody-like molecules.

The term "specifically binds" refers to the ability of the antibody to bind to at least one polypeptide of the present invention but not significantly to known proteins in the sample/organism to be tested.

As used herein, the term "epitope" refers to a region of a polypeptide of the invention which is bound by the antibody. An epitope can be administered to an animal to generate antibodies against the epitope, however, antibodies of the present invention preferably specifically bind the epitope region in the context of the entire polypeptide.

If polyclonal antibodies are desired, a selected mammal (e.g., mouse, rabbit, goat, horse, etc.) is immunised with an immunogenic polypeptide of the invention. Serum from the immunised animal is collected and treated according to known procedures. If serum containing polyclonal antibodies contains antibodies to other antigens, the polyclonal antibodies can be purified by immunoaffinity chromatography. Techniques for producing and processing polyclonal antisera are known in the art. In order that such antibodies may be made, the invention also provides polypeptides of the invention or fragments thereof haptenised to another polypeptide for use as immunogens in animals.

Monoclonal antibodies directed against polypeptides of the invention can also be readily produced by one skilled in the art. The general methodology for making monoclonal antibodies by hybridomas is well known. Immortal antibody-producing cell lines can be created by cell fusion, and also by other techniques such as direct transformation of B lymphocytes with oncogenic DNA, or transfection with Epstein-Barr virus. Panels of monoclonal antibodies produced can be screened for various properties; i.e., for isotype and epitope affinity.

An alternative technique involves screening phage display libraries where, for example the phage express scFv fragments on the surface of their coat with a large variety of complementarity determining regions (CDRs). This technique is well known in the art.

Other techniques for producing antibodies of the invention are known in the art.

Antibodies of the invention may be bound to a solid support and/or packaged into kits in a suitable container along with suitable reagents, controls, instructions and the like.

In an embodiment, antibodies of the present invention are detectably labeled. Exemplary detectable labels that allow for

31

direct measurement of antibody binding include radiolabels, fluorophores, dyes, magnetic beads, chemiluminescers, colloidal particles, and the like. Examples of labels which permit indirect measurement of binding include enzymes where the substrate may provide for a coloured or fluorescent product. Additional exemplary detectable labels include covalently bound enzymes capable of providing a detectable product signal after addition of suitable substrate. Examples of suitable enzymes for use in conjugates include horseradish peroxidase, alkaline phosphatase, malate dehydrogenase and the like. Where not commercially available, such antibody-enzyme conjugates are readily produced by techniques known to those skilled in the art. Further, exemplary detectable labels include biotin, which binds with high affinity to avidin or streptavidin; fluorochromes (e.g., phycobiliproteins, phycoerythrin and allophycocyanins; fluorescein and Texas red), which can be used with a fluorescence activated cell sorter; haptens; and the like. Preferably, the detectable label allows for direct measurement in a plate luminometer, for example, biotin. Such labeled antibodies can be used in techniques known in the art to detect polypeptides of the invention.

EXAMPLES

Example 1

Materials and Methods

Microscopic Analysis of Seedling Rust Infection

Plants were grown in a growth chamber maintained at 4-8° C. under a 12 hour light and dark regime. Seedlings were

32

PDR was amplified using the primers Lr34_RT_fl: 5'-catcaagattcaccgcctgtgc-3' (SEQ ID NO:12) and Lr34_RT_rl: 5'-gaagcctagcaacttcacgaggc-3' (SEQ ID NO:13) at an annealing temperature of 70° C.

For the Northern blot hybridization analysis, 15 µg of total RNA per sample was blotted on a membrane (Hybond-XL, Amersham Biosciences). The probe HvS40 (Spielmeyer et al., 2002) was ³²P-labeled at 65° C. using the NEBlot® kit (New England BioLabs). Membranes were washed with a 0.5× SSC, 0.1% SDS solution at 65° C. and exposed to hypersensitive X-ray films (BioMax MS film, Kodak).
Rapid Amplification of cDNA Ends (RACE)

To determine the exact start of the cDNA, a 5' RACE approach was used. Poly A⁺ RNA was purified from 300 µg of total RNA using the Oligotex® mRNA Mini Kit (Qiagen). Reverse transcription was done using the SMART™ RACE cDNA Amplification Kit (Clontech Laboratories), where an adapter was ligated to the 5' end of the cDNA. Amplification of the 5' end was done using an adapter specific primer and the gene specific primer ABC_5RACE_r2: 5'-gcggggcccacatcatctcgcc-3' (SEQ ID NO:14).

Example 2

Genetic Mapping of Lr34

Plant Materials

Three backcross populations were produced and used for genetic mapping of Lr34. The parental parents for the backcrossing, scored phenotypes, population size, and markers mapped on each population are summarized in Table 2.

TABLE 2

The three backcross populations that have been used for the high-resolution genetic mapping of Lr34.					
+Lr34 parent	-Lr34 parent	+Lr34 backcross line	origin	phenotypic scoring	nr. of plants markers mapped
Forno	Arina	Arina Lr34 (Arina*3/Forno)	Swiss winter wheat	Leaf tip necrosis, leaf rust infection	1728 BE493812, SWSNP1, SWSNP2, SWSNP3, SWDEL1, SWDEL2, SWDEL3, SWM10, csLVMS
PI58548	Thatcher	RL6058 (Thatcher*6/PI58548)	Chinese landrace	Leaf, stripe, and stem rust; powdery mildew	1152 Gwm1220, BJ280740, csLVD13, csLVD2, csLVMS, BF473324, csLV34
Parula	Avocet	Avocet Lr34 (Avocet*5/Parula)	CIMMYT	Leaf and stripe rust, leaf tip necrosis	1152 Gwm1220, csLVD13, csLVD2, csLVE17, csLVMS, csLV34

inoculated at the two leaf stage using leaf rust culture 467 and transferred into a humidity chamber (with a temperature range of 16-20° C.) for 24 hours and returned to the 4-8° C. growth chamber. For microscopic visualisation of internal infection structures, the first leaf tissue was autoclaved in 1M KOH, washed in 50 mM KPO₄ and stained with a 50 mM KPO₄ (pH 7.8) solution containing 20 µg/ml of wheat germ agglutinin (WGA) conjugated to the fluorophore alexa 488 (Invitrogen, USA) staining solution. All WGA-alexa stained tissue was examined under blue light excitation.

RNA Isolation for Semi-Quantitative PCR and Northern Blot

Total RNA was extracted from leaves using a TRIzol solution (38% Phenol, 0.8M guanidine thiocyanate, 0.4M ammonium thiocyanate, 0.1M sodium acetate pH 5 and 10% glycerol). First-strand cDNA for RT-PCR was synthesized using Superscript II reverse transcriptase (Invitrogen). A specific fragment for semi-quantitative RT-PCR of the 5' end of the

The 'Arina×Formo' fine-mapping population was developed by crossing the highly resistant Swiss winter wheat cultivar 'Formo' with the susceptible Swiss winter wheat cultivar 'Arina'. Subsequent backcrossing to Arina and several generations produced by self-fertilization resulted in 103 plants that were "backcross two F4" (BC2F4) containing Lr34 and on average 12.5% of the 'Formo' genome in an otherwise Arina genetic background. These plants were analyzed for the presence of the Lr34 chromosomal segment from 'Formo' using two flanking RFLP markers BE493812 and BF473324. One of these plants containing the Lr34 region was again crossed to 'Arina' and the progeny selfed to produce 1728 BC3F2 plants, having on average 6.25% of the 'Formo' genome. Recombinants were selected using the two flanking markers BE493812 and SWM10. Phenotyping of the 'Arina×Formo' population was done at Agroscope Reckenholz, Zurich, Switzerland during 2006 (BC3F3) and 2007

(BC3F4). Infection rows containing a mixture of susceptible varieties were inoculated with urediniospores of the Swiss leaf rust isolates Nr. 90035, 91047, 93003, 93012, 94015, 95001, 95012, 95028, 95037, 95039, 95219, 95251, 96002, 96004, 96209, and 96257. Disease rating was done on two replicas.

The Thatcher×RL6058 (Thatcher Lr34) and Avocet×Avocet Lr34 high resolution mapping family, disease evaluation in Australia and at CIMMYT, Mexico were as described in Lagudah et al. (2006) and Spielmeier et al. (2002). Other genetic stocks used in this work were the near isogenic lines 'Thatcher', 'Thatcher Lr34' (=RL6058, Thatcher*6/PI5848), 'Arina', 'Arina Lr34' (Arina*3/Formo).

Marker Development for Genetic Mapping

New molecular markers for mapping were generated by exploiting the syntenic information of rice, the model grass *Brachypodium sylvaticum* and the diploid D-genome progenitor *Aegilops tauschii* as described by Bossolini et al. (2006).

To gain physical information of the Lr34 target interval, a partially fingerprinted Bacterial Artificial Chromosome (BAC) library of *Aegilops tauschii* (J. Dvorak, U C Davis) was screened using wheat ESTs related to genes from the syntenic region of rice and *Brachypodium sylvaticum*. Thirteen BAC clones from three different contigs (HI057C6/HD036L7/HD102K14/HI056G21/HD062G18/HI031F14/HI135B2/RI004I15/RI042I4/HI148C23/BB045B13/HB067N4/BB062G18) were sequenced by low-pass sequencing using an ABI® 3730 sequencer (Applied Biosystems). Sequences were assembled using PHRAP and mined for simple sequence repeats (SSR). SSRs were amplified by designing primers in the flanking regions (Table 3).

PCR products were analyzed using the LiCOR® DNA Sequencer 4200. Polymorphic SSRs were identified and designated with prefixes "SWM" or "cs". Sequence tagged sites were developed by designing primers on low-copy sequences. Locus-specific probes were sequenced and mined for single nucleotide polymorphisms (SNP) and insertion/deletions (InDel). Polymorphic SNP-based markers and InDels were designated as Swiss Wheat SNP (SWSNP) and

Swiss Wheat Deletion (SWDEL), respectively. Primer sequences for the PCR based markers mapped on the populations are summarized in Table 3. Additional low copy probes, csLVD2, csLVD13, csLVE17, for RFLP analysis were isolated from shotgun plasmid libraries from the *Ae tauschii* BAC contigs by screening with total genomic DNA from *Ae tauschii*. Recombinant plasmids where no DNA hybridization signals were detected after an overnight exposure were selected as potential low copy probes.

Using these genetic markers and the mapping populations for Lr34, the high-resolution mapping revealed a 0.15 cM target interval for Lr34 flanked by genetic markers XWSNP3 and XcsLVE17 (FIG. 1). Several markers (FIG. 1) were cosegregating with Lr34.

Example 3

Mutagenesis and Isolation of Lr34 Mutants

Seeds of the Lr34 isoline, 'Lalbahadur Lr34' were irradiated using a ⁶⁰Co source at a dosage of 20 krad and the subsequent M1-M5 generations evaluated at CIMMYT, Mexico and in Australia as reported in Spielmeier et al. (2002). Eight mutants were identified from the gamma-irradiated population. These were analysed using some of the new genetic markers (Example 2). Of the eight mutants, six were interstitial deletions spanning the Lr34/Yr18/Pm38/Ltn1 locus while the two mutants designated m19 and m21 showed no loss of markers in the aforementioned genetic locus. Mutants m19 and m21 were therefore subjected to further analysis utilising the newly identified markers and cosegregating genes.

Sodium azide mutants were developed using seed from a single head of an RL6058 plant grown in the glasshouse to multiply pure seed stocks for mutagenesis. Seeds were pre-soaked for 12 hrs at 4° C. before treating the grains in an oxygenated solution of 7 mM sodium azide at pH 3.0 for 2 hrs. The grains were rinsed and planted in the field. The M2 progenies were planted as single ear rows and scored for stripe, leaf and stem rust infection in the field in the presence of the pathogens.

40

Six susceptible mutants were isolated and rated 70MS to 90MS for stripe rust, 50MS to 80MS for leaf rust and 50MS for stem rust under field conditions. Two mutants 4C (glycine to glutamic acid at amino acid position 1030 of SEQ ID NO:1) and 2G (glycine to aspartic acid at amino acid position 889 of SEQ ID NO:1) were the result of single nucleotide transitions that resulted in a single amino acid change within the second predicted nucleotide binding domain (FIGS. 3 and 5). These mutants showed only partial loss of resistance to leaf rust when examined microscopically (Example 1). Mutant 2B incorporated a single nucleotide transition in exon 11 (FIG. 3) that resulted in an early stop codon. Three mutants 3E, 4E and 2F were the result of single nucleotide transitions at splice junctions resulting in mis-spliced transcripts. The retention of introns in mutants 3E and 4E introduced early stop codons near the 5' end which was predicted to result in a non-functional protein. At the microscopic level mutants 3E and 4E were fully susceptible to leaf rust and indistinguishable from the susceptible near-isogenic line 'Thatcher'. The transcript of mutant 2F lost the second last exon (FIG. 3) which was predicted to delete 85 amino acids from the second transmembrane domain. The 2F mutant was more susceptible to leaf rust than the susceptible control 'Thatcher' during the early infection process.

The lack of resistance resulting from loss of a functional Lr34 protein observed in the mutation study is consistent with

analysis of the Lr34 gene from Jagger. Jagger has Lr34-associated alleles of the csLV34 marker but is susceptible to leaf rust and stripe rust. Sequencing of the Lr34 gene in Jagger identified a G/T point mutation that resulted in a premature stop codon. Consequently, the predicted protein of cultivar Jagger lacks 185 amino acids of the C-terminus and this allele is most likely not functional. This point mutation probably occurred in a resistant cultivar that carried the +Lr34 allele.

Example 4

Physical Information of the Target Interval and Identification of the Lr34 Gene

Two BAC libraries of the +Lr34 (resistant) cultivar 'Chinese Spring' and the -Lr34 (susceptible) cultivar 'Renan' (INRA, Toulouse, France) were screened using PCR probes covering the target interval between the two flanking markers SWSNP3 and csLVE17. The 420 kb physical interval containing both flanking markers was fully sequenced in the resistant hexaploid wheat cultivar 'Chinese Spring'. To do this, four 'Chinese Spring' BAC clones, namely 345C22, 93N17, 1964C18 and 413N16, and the 'Renan' clone 656106 were selected and fully sequenced at the Genome Sequencing Center, St. Louis, Mo., USA.

Sequence analysis revealed the presence of a gene-rich island containing ten open reading frames (FIG. 2) encoding

proteins with homologies to two glycosyl transferases, two cysteine proteinases, two receptor lectin kinases, two cytochrome P450 proteins, a hexose carrier and an ATP binding cassette (ABC) transporter. None of these genes was present in the syntenic region in *Brachypodium sylvaticum* and only the hexose carrier was found to be conserved in the homologous region on rice chromosome 6 (rice gene Os06g0141000). Significantly and surprisingly, none of the genes appeared to be typical LRR-NBS type genes of the class commonly associated with pathogen resistance in plants. Therefore, none of the coding regions was an obvious candidate for encoding Lr34.

To determine whether one of these candidate genes corresponded to Lr34, locus-specific PCR-amplified regions corresponding to the ten candidate genes on each of the eight Lr34 mutants were sequenced. Candidate genes were amplified by developing locus-specific PCR probes, amplified from resistant and susceptible cultivars as well as on the eight Lr34 mutants, and sequenced. The mutants were the six azide mutants in the genetic background of 'Thatcher Lr34' and two gamma irradiation mutants in the 'Lalbahadur Lr34' background (Example 3).

All of the mutant lines showed a sequence alteration in the open reading frame encoding the ABC transporter (FIG. 3). The three azide mutants 2F, 3E and 4E all had a G to A transition at an intron-exon boundary leading to splice site mutations (FIG. 7, showing retained introns). Transitions in the two azide induced mutants 2G and 4C resulted in amino acid substitutions and line 2B carried a premature stop codon in exon 11. The two gamma irradiation mutants m19 and m21 each showed a 1 bp deletion in exon 10 and 23, respectively, leading to frame shifts and premature stop codons (FIG. 3).

To remove the possibility of additional mutation sites in the other cosegregating genes, DNA fragments covering 12.7 kb of the other nine candidate genes and intergenic regions on the four azide mutants 2B, 3E, 4C and 4E were sequenced, without finding any additional sequence alterations. Similarly, sequencing showed that the gamma-radiation generated mutants m19 and m21 did not harbour any sequence changes in the coding regions of the remaining nine candidate genes. Therefore, the possibility that the eight mutations found in the ABC transporter were due to a very high mutation frequency in these lines could be excluded, and we concluded that the ABC transporter was responsible for conferring the durable Lr34 disease resistance.

Lr34 co-segregated with partial resistance to adult plant stripe rust (Yr18), powdery mildew (Pm38) as well as leaf tip necrosis (Ltn1). All of the mutants were more susceptible, as adult plants, to stripe rust and powdery mildew attributed to the loss of Yr18 and Pm38 and also exhibited complete or partial loss of Ltn1. These observations represented an important finding, in that eight independent mutations within a single ABC transporter gene encoding the Lr34 resistance also accounted for Yr18/Pm38/Ltn1, and demonstrated that a single gene conferred resistance to multiple pathogens.

The protein coding sequence of Lr34 spanned 11.7 kb in the wheat genome. Sequencing of the entire cDNA and comparison of the nucleotide sequence with the genomic sequence (SEQ ID NO:3) revealed that Lr34 had 24 exons. The gene contained 23 introns including a large intron of 2.5 kb between exons 4 and 5 (FIG. 3). The protein encoded by Lr34 from the resistant cultivar Chinese Spring had 1401 amino acids (SEQ ID NO:1), while the protein from the susceptible cultivar Renan had 1402 amino acids (SEQ ID NO:4, FIG. 4). Comparison of the amino acid sequence with other ABC transporters showed that the Lr34 proteins belonged to the Pleiotropic Drug Resistance (PDR) subfam-

ily of ABC transporters. PDRs share a common basic structure containing two distinct domains: a cytosolic nucleotide binding domain (NBD) that contains the conserved motifs "Walker A" and "Walker B" involved in ATP binding and hydrolysis, and a hydrophobic transmembrane domain (TMD) involved in translocating the substrate. Both domains are present in duplicate, therefore the structure of PDRs is designated [NBD-TMD]₂ (FIG. 5).

The PDR family is only found in fungi and plants. Fifteen PDR-like genes have been identified in the genome of *Arabidopsis* and 23 members were described in rice (Crouzet et al., 2006). It is known that PDRs confer resistance to various drugs, but little is known about the substrate specificity of this protein class (Rogers et al., 2001). It has previously been reported that PEN3/PDR8, a PDR from *Arabidopsis*, contributes to nonhost resistance to pathogens (Stein et al., 2006). The closest Lr34 homolog in rice is PDR23, showing 88% identity on the amino acid level (Table 4). In *Arabidopsis*, Lr34 shows closest homology to the two transporters PDR5 and PDR9, with 56% identity. The alignment of these amino acid sequences is shown in FIG. 6.

The present inventors next determined the sequence differences between the Lr34 alleles in cultivars with or without Lr34-based resistance. Comparison of genomic sequences of the PDR in the +Lr34 cultivar 'Chinese Spring' and the -Lr34 French winter wheat cultivar 'Renan' revealed that the gene was present in both wheat varieties. There were only three polymorphisms in the coding sequences between these two lines (FIG. 3). One SNP was located in the large intron 4. The other two sequence alterations were located in exons 11 and 12. A deletion of three base pairs 'TTC' found in exon 11 in 'Chinese Spring' results in the deletion of a phenylalanine residue whereas a second SNP in exon 12 converted a tyrosine to a histidine in the resistant cultivar. Both sequence differences located in exons affect the first transmembrane domain connecting the two nucleotide binding domains and they may alter the structure and binding specificity of the transporter (FIG. 4). Sequence comparison of 2 kb of the putative promoter regions did not reveal any differences between the resistant and susceptible alleles.

To find out which of these three sequence differences were required for determining the resistance, their diagnostic value was determined on a set of +/-Lr34 genotypes sourced from different Lr34 breeding lineages (Table 5). All the +Lr34 lines showed the same haplotype as 'Chinese Spring' and all the -Lr34 lines were identical to that of 'Renan'. Hence, all of the three reported sequence differences may be important for determining the resistance conferred by Lr34, although we have no evidence that the SNP in intron 4 affects the splice efficiency of either of the alleles. Given that the same haplo-

type was found in the Lr34 PDR-ABC transporter gene for the spring wheats from the South/North American breeding programs, winter wheats from Europe and the oriental Lr34 genotypes (Table 5), we infer that a single event likely accounts for the origin of Lr34 in a wheat landrace. Evidence linking the American and European wheats containing Lr34 is traced back to the founder sib cultivars, 'Mentana' and 'Ardito' developed at the beginning of the last century (Kolmer et al., 2008).

When testing the diagnostic potential of the SNP located in intron 4 a third allele was identified. The winter wheat cultivars Zinal, Allalin and Galaxie, as well as the spelt (*Triticum spelta*) varieties Ostro and Rouquin showed the +Lr34 haplotype in intron 4, but had the -Lr34 haplotype for the two markers in exons 11 and 12. Hence, these lines form a third haplotype. Interestingly, the reciprocal allele (T, for SNP in intron 4 and +Lr34 for both exon markers) was never observed. This finding suggests that this haplotype arose through mutation rather than recombination and probably represents the progenitor of the functional +Lr34 haplotype.

Example 5

Expression of Lr34

Lr34 is a model for adult plant resistance, which is not effective at the seedling stage under normal field conditions. To determine whether this was related to lower expression of Lr34 at the seedling stage, semi-quantitative RT-PCR was used to measure expression levels at various stages of plant development using the near isogenic lines 'Thatcher' and 'Thatcher Lr34'. The PDR was expressed at very low levels in 14 days old seedlings grown at 20° C. whereas the expression level was significantly higher in flag leaves of adult plants

after 53 and 63 days (FIG. 7). There was no substantial difference in expression between resistant and susceptible plants which was in agreement with the finding that there were no sequence differences in the promoter regions of the resistant and susceptible alleles. Interestingly, the unspliced product was observed to accumulate in adult plants after 63 days. Also, an altered transcript in 'ThatcherLr34' had 92 nucleotides missing from exon 10 which was predicted to disrupt the reading frame and result in a truncated protein.

It has been shown that Lr34 confers resistance at the seedling stage to leaf rust cultures at low temperatures (Dyck and Samborski, 1982). Analysis of the mutants and the parental Lr34 lines grown, as seedlings, at low temperatures (4-8° C.) and infected with leaf rust revealed a "slow rusting" resistance response with the intact Lr34 gene. In the initial 2-3 weeks post infection, differences in colonized mesophyll cells between mutants m19, m21 and Lalbahadur Lr34' were insignificant. However by the fifth week the colonized area had extended at least four times in size with mutants m19 and m21 when compared with the active Lr34 gene. External symptoms of sporulation in seedlings were evident in the mutants by the fifth week whereas the presence of the active Lr34 gene delayed visible symptoms until after the sixth week post infection. This observation was akin to the longer latency period that was characteristic of the slow rusting mechanism of Lr34 resistance.

Lr34 conferred a broad spectrum resistance against several obligate biotrophic pathogens including fungi from the Ascomycetes and Basidiomycetes. Rubiales and Nicks (1995) reported that Lr34 was associated with reduced intercellular hyphal growth but not with a hypersensitive response or papilla formation. The eight Lr34 mutants were affected in their resistance against leaf rust, stripe rust and powdery mildew and they did not show leaf tip necrosis as described above. Infection experiments revealed that the level of resistance was coupled to the development of leaf tip necrosis and that artificial inoculation with leaf rust before emergence of leaf tip necrosis led to more severe disease symptoms than infections at later time points. These observations suggested that the resistance mechanism of Lr34 was due to a general physiological effect rather than to a 'classical' resistance mechanisms involving recognition of pathogen elicitors or secretion of antifungal components.

From this, a hypothesis was formed that the durable resistance conferred by Lr34 was associated with and at least partly due to premature senescence of the flag leaf, in particular the leaf tips. In contrast to necrosis, senescence is a highly controlled process including the remobilization of nutrients and the degradation of chlorophyll. It was considered that premature leaf senescence starting from the leaf tip could hamper the feeding of the pathogen from host cells and might retard its growth and multiplication. Senescence-related genes were therefore analysed in the wheat plants with or without Lr34.

The gene HvS40 was known to be highly upregulated during senescence in barley (Krupinska et al., 2007). A probe corresponding to this gene was prepared from cDNA. Using this probe in a Northern blot hybridization analysis revealed that wheat HvS40 was highly expressed in flag leaf tips of 'Thatcher Lr34' but not of 'Thatcher' in 63 days old plants. Furthermore the gene was down-regulated or not expressed in the six Lr34 azide mutants (FIG. 8). This was strong evidence that Lr34 regulated senescence of flag leaves in adult wheat plants. On the other hand, microscopic observations have indicated the build up of cell wall appositions following leaf

rust infection of Lr34 genotypes. It is therefore likely that Lr34 mediated resistance affected pathogen development in a more complex way.

The cloning of Lr34 is the first reported cloning of a multi-pathogen resistance QTL from wheat, which includes Lr34, Yr18, Pm38, Ltn1 and demonstrated this was controlled by a single gene. An ABC transporter of the PDR subfamily was identified as the gene being responsible for conferring this durable adult plant resistance. Resistant and susceptible alleles differed by only three minor sequence alterations within the coding sequence. The resistant allele was thought to accelerate senescence of flag leaf tips and therefore compromise nutrient uptake by obligate biotrophic pathogens.

Example 6

Related Genes from Wheat and Other Species

The homoeologous genes from the A and B genomes of wheat, and genes encoding homologs in other species were isolated by using probes derived from the wheat Lr34 gene to probe cDNA or genomic libraries. The homoeologous genes from the A and B genomes were isolated. A homoeologous gene was isolated from *Aegilops tauschii*, a diploid cereal (D genome) related to wheat (SEQ ID NO:6). Other related sequences were identified from EST databases, containing partial sequences (Table 6).

TABLE 6

A related gene member was also detected in barley when a cDNA probe derived from the 3' half of the gene was hybridized to genomic barley DNA under standard conditions.

The present inventors have also determined the homeolog of Lr34 present on chromosome 7B of wheat. The protein sequence of this homeolog is provided as SEQ ID NO:63 and the cDNA sequence as SEQ ID NO:64.

Example 7

Production of Transgenic Wheat Expressing an Exogenous Adult Plant Pathogen Resistance Gene

In order to produce transgenic wheat, the polynucleotide comprising a sequence of nucleotides as provided in SEQ ID

NO:2 is sub-cloned into a pPlex vector (Schunmann et al., 2003) such that the subterranean clover stunt virus promoter is able to drive gene transcription in a wheat cell.

Transformation of wheat embryos from the cultivar Bob-white 26 is performed according to the method of Pellegrineschi et al. (2002). To confirm that the plants that were produced contained the construct, PCR analysis is performed on genomic DNA extracted from leaves using a FastDNA® kit (BIO 101 Inc., Vista, Calif., USA) according to the suppliers instructions. The DNA is eluted into 100 µl sterile deionized water and 1 µl used in PCR.

Plants are tested for enhanced resistance to plant pathogens such as *Puccinia graminis* f. sp. *tritici* (which causes stem rust), *Puccinia striiformis* (which causes stripe rust) and/or *Puccinia recondite* f. sp. *tritici* (which causes leaf rust).

It will be appreciated by persons skilled in the art that numerous variations and/or modifications may be made to the invention as shown in the specific embodiments without departing from the spirit or scope of the invention as broadly described. The present embodiments are, therefore, to be considered in all respects as illustrative and not restrictive.

The present application claims priority from AU 2008904364 filed 25 Aug. 2008, the entire contents of which are incorporated herein by reference.

All publications discussed and/or referenced herein are incorporated herein in their entirety.

Any discussion of documents, acts, materials, devices, articles or the like which has been included in the present specification is solely for the purpose of providing a context for the present invention. It is not to be taken as an admission that any or all of these matters form part of the prior art base or were common general knowledge in the field relevant to the present invention as it existed before the priority date of each claim of this application.

The invention claimed is:

1. A transgenic cereal plant which has integrated into its genome an exogenous polynucleotide encoding an Lr34 adult plant pathogen resistance polypeptide comprising an amino acid sequence at least 95% identical to the amino acid sequence set forth as SEQ ID NO:1, wherein the adult plant pathogen resistance polypeptide provides enhanced resistance to a plant pathogen when compared to an isogenic cereal plant lacking the exogenous polynucleotide, and wherein the pathogen is one or more of the following pathogens: *Bipolaris sorokiniana*, *Erysiphe graminis* f. sp. *tritici*, *Puccinia graminis* f. sp. *tritici*, *Puccinia striiformis* and *Puccinia recondita* f. sp. *tritici*.

2. The transgenic cereal plant of claim 1 wherein the plant is a wheat plant.

3. The transgenic cereal plant of claim 1, wherein the amino acid sequence of the Lr34 adult plant pathogen resistance polypeptide is at least 98% identical to the amino acid sequence set forth as SEQ ID NO:1.

4. The transgenic cereal plant of claim 1, wherein the amino acid sequence of the Lr34 adult plant pathogen resistance polypeptide comprises the amino acid sequence set forth as SEQ ID NO:1.

5. The transgenic cereal plant of claim 4 wherein the plant is a wheat plant.

6. A transgenic cereal seed which has integrated into its genome an exogenous polynucleotide encoding an Lr34 adult plant pathogen resistance polypeptide comprising an amino acid sequence at least 95% identical to the amino acid sequence set forth as SEQ ID NO:1, wherein the adult plant pathogen resistance polypeptide provides enhanced resistance to a cereal plant produced from the seed to a plant pathogen when compared to an isogenic cereal plant lacking the exogenous polynucleotide, and wherein the pathogen is one or more of the following pathogens: *Bipolaris sorokiniana*, *Erysiphe graminis* f. sp. *tritici*, *Puccinia graminis* f. sp. *tritici*, *Puccinia striiformis* and *Puccinia recondita* f. sp. *tritici*.

7. The transgenic cereal seed of claim 6 wherein the seed is a wheat seed.

8. The transgenic cereal seed of claim 6, wherein the amino acid sequence of the Lr34 adult plant pathogen resistance polypeptide is at least 98% identical to the amino acid sequence set forth as SEQ ID NO:1.

9. The transgenic cereal seed of claim 6, wherein the amino acid sequence of the Lr34 adult plant pathogen resistance polypeptide comprises the amino acid sequence set forth as SEQ ID NO:1.

10. The transgenic cereal seed of claim 9 wherein the seed is a wheat seed.

11. A method of producing a transgenic cereal plant which has integrated into its genome an exogenous polynucleotide encoding an Lr34 adult plant pathogen resistance polypeptide

comprising an amino acid sequence at least 95% identical to the amino acid sequence set forth as SEQ ID NO:1, the method comprising

- i) introducing said exogenous polynucleotide encoding the Lr34 adult plant pathogen resistance polypeptide into a cereal plant cell, wherein the polynucleotide is operably linked to a promoter, and
- ii) generating a transgenic cereal plant from the cell, thereby producing the transgenic cereal plant, wherein the adult plant pathogen resistance polypeptide provides enhanced resistance to the plant to a plant pathogen when compared to an isogenic cereal plant lacking the exogenous polynucleotide, and wherein the pathogen is one or more of the following pathogens: *Bipolaris sorokiniana*, *Erysiphe graminis* f. sp. *tritici*, *Puccinia graminis* f. sp. *tritici*, *Puccinia striiformis* and *Puccinia recondita* f. sp. *tritici*.

12. The method of claim 11, wherein the cereal plant is a wheat plant.

13. The method of claim 11, wherein the amino acid sequence of the Lr34 adult plant pathogen resistance polypeptide is at least 98% identical to the amino acid sequence set forth as SEQ ID NO:1.

14. The method of claim 11, wherein the amino acid sequence of the Lr34 adult plant pathogen resistance polypeptide comprises the amino acid sequence set forth as SEQ ID NO:1.

15. The method of claim 14, wherein the cereal plant is a wheat plant.

16. A method of producing a transgenic cereal plant part which has integrated into its genome an exogenous polynucleotide encoding an Lr34 adult plant pathogen resistance polypeptide comprising an amino acid sequence at least 95% identical to the amino acid sequence set forth as SEQ ID NO:1, the method comprising,

- a) growing the transgenic cereal plant of claim 1, and
- b) harvesting a transgenic cereal plant part from the plant.

17. The method of claim 16, wherein the cereal plant is a wheat plant.

18. The method of claim 16, wherein the amino acid sequence of the Lr34 adult plant pathogen resistance polypeptide is at least 98% identical to the amino acid sequence set forth as SEQ ID NO:1.

19. The method of claim 16, wherein the amino acid sequence of the Lr34 adult plant pathogen resistance polypeptide comprises the amino acid sequence set forth as SEQ ID NO:1.

20. The method of claim 19, wherein the cereal plant is a wheat plant.
